Dr. H. J. F. SIMSON: 1. Fibroid Tumour of the Uterus undergoing Red Degeneration and necessitating hysterectomy at about four and a half months 2 A similar specimen causing miscarriage at five months Hysterectomy for hæmorrhage seven weeks later At the commencement of pregnancy the fibroid was of the size of half a walnut 3 Fibroid of Uterus causing impaction from growth in lower uterine segment and forward displacement of the right uterine artery 4 Carcinoma of Body of Uterus with Pyometra 5 Sarcoma of Body of Uterus with Polypoidal Growth 6 Cauliflower Growth of Cervix 7 Cauliflower Growth of Cervix—cauterised before removal 8 Intracervical Carcinoma—atrophic uterus 9 Intracervical Carcinoma spreading towards bladder

Mr S G MACDONALD Closed Renal Tuberculosis showing upper portion of kidney completely shut off from the ureter so that the urine was sterile and free from pus or tubercle bacilli In the early history of renal tuberculosis latent intervals in the symptoms and apparent progress of the disease were commonly noticed A patient suffered from pyuria, *frequency of micturition &c , after a varying* interval the symptoms subsided and the urine became normal, but sooner or later the symptoms recurred corresponding to definite pathological changes going on in the kidney —Mr MCADAM ECCLES remarked on the interest of this exhibit because of the apparently healthy condition of the urinary passages below the kidney

Dr A K THOMSON took the opportunity afforded by this meeting of introducing The Man Who Grows who claims to be able to increase his height at will by 7 in to increase the length of his arms by 4 to 15 in , and to elongate the neck by 2 in without any dislocation or separation of joints This acrobat stated he could never be sure exactly how much he would accomplish at a given demonstration and that the 7½ in referred to above was his record He then proceeded to demonstrate his power of elongating while in the standing position and although he did not attain the figures quoted the exhibition was remarkable and interesting On submitting himself to examination he appeared to possess within physiological limits an abnormal degree of spinal mobility and an unusual control over muscles which are but rarely voluntarily exercised

UNITED SERVICES MEDICAL SOCIETY

Regimental and Field Ambulance Training

A MEETING of this society was held at the Royal Army Medical College on Feb 12th Fleet Surgeon P W BASSETT SMITH C B R N the President being in the chair

Major J OLDFIELD R A M C (T) read a paper on Regimental and Field Ambulance Training Discussing the training of medical officers attached to combatant units in the Territorial Force, he drew a comparison between these officers and the medical officers of field ambulances pointing out that the former, after completing their first training camp or course of instruction, may remain for years on the strength and yet never do a single duty for the battalion or come into contact with any of its officers or men Even the maximum of a fortnight every two years in contact with their men and their work could not be considered at all sufficient to enable officers to keep in real touch with their duties The case of the field ambulance officer is very different He is obliged to attend camp once in three years and this is expressly laid down as the minimum with the implied suggestion that he should attend oftener The speaker laid great stress on this point as he considered an efficient camp training to be the only real way in which a medical officer could be fitted for active service duties The point then is that a regimental medical officer is encouraged not to attend camp more often than once in every two years whereas the obligation is laid upon the field ambulance officer to attend camp not less than once in three years No doubt the intention was to lighten the duties of busy practitioners willing to join the Territorial Force by providing a regiment with two medical officers attending training in alternate years but the event has proved that it is easier to get the *same class of busy men to go into camp year after year for the full fortnight* in field ambulances than to get the full complement of regimental officers for camp duty every second year The mere fact therefore of "making it easy" is not an inducement which attracts men to join the Territorial Force Now, what are the duties that a regimental medical officer is expected to perform? It is often and fallaciously supposed that a regimental doctor s only duties are to attend to the sick of his unit in times of peace and to look after the wounded during battle The truth however, is very different It is intended that he should be the commanding officer s right hand man in all matters affecting the health of the troops or prevention of disease amongst them He is responsible for the custody and use of *medical and surgical stores and for the training* and duties of the Royal Army Medical Corps men attached to the unit He has to examine recruits in camp see the sick, and be ready to deal with infectious cases and accidents according to the routine laid down in regulations He has also to familiarise himself with his duties in action and to train the bandsmen in bearer drill and first aid All these duties are very important and it is hard to imagine how they are to be thoroughly performed by an officer to whom no incentive is held out to put in more than the minimum of training laid down in regulations Major *Oldfield* recounted his own experiences of both regimental and field ambulance work and described the increased efficiency with which he performed regimental duty during a temporary return to it after having served in a medical unit He suggested 1 That the one portal of entry into the medical service of the Territorial Force should be the field ambulance 2 That from the field ambulances officers should volunteer for regimental duty not earlier than the close of their first year s training and 15 days camp 3 That a regimental medical officer should not be debarred from an annual camp but rather encouraged to attend it Where there are two medical officers in a battalion one should be attached to a field ambulance for his camp and the other trained with his regiment 4 That every medical officer should train one year in three with a field ambulance in camp 5 That the annual training as to drills riding &c should apply to all Royal Army Medical Corps (Territorial) officers When they live at a distance from drill halls travelling expenses should be allowed 6 That brevet rank should sometimes be conferred on officers showing zeal and ability coupled with any special excellence as an incentive to effort

The following officers took part in the *discussion* — Colonel J HARPER A M S (T) Lieutenant Colonel W SALISBURY SHARPE R A M C (T) Major E B WAGGETT, R A M C (T) and Lieutenant Colonel C H BURTCHAELL Major S L CUMMINS Major F S IRVINE and Capt in GRANT of the Royal Army Medical Corps

Major OLDFIELD thanked the officers who had taken part in the discussion and brought the meeting to a close in a brief reply

EDINBURGH MEDICO CHIRURGICAL SOCIETY

Exhibition of Patient —The Position of the Radiographer in Relation to the Physician and Surgeon —Adjourned Discussion on Bone Tuberculosis

A MEETING of this society was held on Feb 5th Mr J M COTTERILL the President being in the chair

Dr EDWIN BRAMWELL exhibited a patient a single woman the subject of Congenital Syphilis She complained of weakness of both hands , this was first noticed at the age of one year and was said to have come on gradually though it had not progressed On examination all the small muscles of both hands appeared to be absent The *flexors and extensors of the fingers and wrists were on* the contrary quite well developed There was no alteration in the reflexes or sensation Dr Bramwell was of opinion that the condition had in all probability been a congenital one and only noticed for the first time at the age of one year The fact that the condition was confined to the small muscles of the hand that all the small muscles of the hand were involved and that the defect was absolutely symmetrical were the points upon which this conclusion was based

Mr ARCHIBALD MCKENDRICK read a *communication on* the Position of the Radiographer in Relation to the Physician and Surgeon He said —In this country there is considerable difference of opinion as to the status of the radiographer There are two prevalent opinions One that the radiographer should be merely an X ray photographer whose duty ends with the production of an X ray picture. The other is, that he should be a radiologist capable of helping his medical and surgical colleagues in diagnosis, and therefore on a level with the consulting pathologist, ophthalmologist, and other medical specialists. With the rapidly increasing work in the X ray department of the Royal Infirmary my colleague, Dr. Hope Fowler, and myself are frequently faced with problems involving the question of status. Are we, for example, to continue giving daily demonstration on the diagnosis of X ray negatives? Have we any right to publish the results of our own investigations of the radiographs taken on behalf of our medical and surgical colleagues? The medical managers of the infirmary have made us personally responsible for the safe-keeping of all radiographs taken in our department. They have further made it incumbent on us to classify and index all these according to region, disease, injury, &c. During the past year nearly 6000 radiographs have been taken in the X ray department and distributed to the various members of the honorary staff. Apart from the enormous amount of clerical work involved in the recording, collecting, and storing of the radiographs, the diagnosis and indexing of these entail an intimate knowledge of anatomy and pathology which is far beyond the sphere of a mere producer of X ray negatives. It is important, therefore, that the professional position of the radiographer be fully discussed and accurately defined. I do not wish to bore the members of this society with details of radiography in other countries, but a brief description of the routine work in the X ray departments of other hospitals will, I think, help us in this discussion. In the hospitals of Paris all consultations on radiographs are held in the X ray department. In Brussels, which is typical of Belgium, all the X ray departments are small. The radiographs are sent to the physicians and surgeons. In Holland generally all consultations are held in the X ray department. In Hamburg, Berlin, Dresden, Leipsic, Munich, Frankfort, and Heidelberg the radiographs are examined in the X ray department jointly by the surgeon and the radiologist. Professor Albers Schönberg of Hamburg goes a step further than most of his continental fellow-workers in so far as he says that he does not consider it advisable for the radiographer to allow the original negative to pass out of his hands. Most of the large towns in this country have adopted the continental method of sending a written report instead of an X ray negative to the physician or surgeon. This routine obtains in London, Liverpool, Leeds, Birmingham, Newcastle, Glasgow, and Aberdeen. The Eleventh Congress of the American Roentgen Society in 1910 resolved that the roentgenologist retains the ownership of the Roentgen plate on the ground that it is an integral part of the documents of the case. The following are the terms of the resolution which was submitted and unanimously adopted by the Eighth Congress of the German Roentgen Society.

1. Roentgenology is a duly authorised medical specialty just as are laryngology, ophthalmology, &c.

2. The roentgenologist is a medical specialist, and as such, in accordance with the usual medical custom, is called in by the physician or the patient as a consultant to make or confirm a diagnosis.

3. The roentgenologist makes use of Roentgen examination in addition to the usual clinical methods. He alone decides what particular procedure shall be employed—radiography, radioscopy, &c.

4. All plates, diapositives, tracings, &c., prepared for the diagnosis of the case are the prope[illegible] histological preparations belong to [illegible]ntgenologist will, as a matter of cou[illegible], to place his plates or prints at the [illegible] or surgeon.

5. The supply of plates or prints to sick clubs or insurance companies is a matter of special arrangement. Further, in urgent cases it is the custom for the roentgenologist to place his plates, &c., at the disposal of the surgeon.

6. The Roentgenologist may at his discretion place a copy of the plate at the disposal of the patient. This, however, is only to be done where it cannot harm or cause anxiety to the patient.

From the foregoing resolutions it will be seen that the question which I have taken the liberty of bringing before this society is no new one. It has been discussed at various congresses: Oporto, February, 1912; Prague, July, 1912; and at the French Congress at Nimes, October, 1912. I therefore lay the matter before you as deserving of your opinions.—Mr. DAVID WALLACE said that the plate was of the greatest value to the surgeon, while a mere report from the radiographer that a fracture existed or that there was a stone in the kidney was of little help. Some of the best plates he had seen had been made by men who were without medical training. It was very much what had happened in connexion with electrical procedures, which had passed out of medical hands into those who were not medical, but who did good work. Mr. Wallace was not at all sure that the method which Mr. McKendrick said had been advocated on the continent was that adopted in the United States. Then these resolutions had been passed at special meetings of radiographers. He was always delighted to have the interpretation of the radiographer, but he expected to have the plate sent to himself for interpretation.—Dr. D. CHALMERS WATSON said that some of the unsatisfactory radiographs were due to the instructions not having been precise enough. If he got a first-class print he had no desire to have the plate.—Mr. J. W. STRUTHERS asked, What position did Mr. McKendrick take up himself? One difficulty was that the radiographer had to be a specialist in everything—lungs, heart, bones, joints. The radiographer to be effective must be a specialist in one branch only—e.g., he might take up the respiratory system and perfect himself in this by using other means as well; if he confined himself to radiography it would not be of much value. The primary duty of the radiographer was to give a good plate.—The PRESIDENT said that the radiographer had first to establish the fact that he was equally skilled, or presumably so, with the surgeon or physician who sent the case before he could claim to discuss that case clinically. He had heard from radiographers the most arrant nonsense in the shape of diagnosis that could possibly be conceived.—In reply Mr. MCKENDRICK said that the infirmary managers had laid upon the radiographers the duty of collecting all the plates taken and of classifying them. Out of 6000 plates taken last year only 3700 had been returned.

Mr. JOHN FRASER, in the adjourned discussion on his communication on Bone Tuberculosis,[1] said: At the last meeting of the society I drew attention to certain points in regard to the etiology and pathology of bone tuberculosis. I attempted to show the importance of the large percentage of cases which owed their origin to infection by tubercle bacilli of the bovine variety, and the necessary relation which such a fact bore to the ingestion of tuberculous milk. I traced the possible paths by which the infection spread to the bones and the joints, and I showed the greater liability of the joints to infection as compared with the bones; I laid special importance upon the fact that the bone marrow frequently becomes degenerated previous to its actual infection. I concluded the demonstration by describing the pathological changes in the bones, secondary to the infection by tubercle. I propose to-night to conclude the subject by very briefly outlining some points in regard to the pathology of tubercular joints. I shall recall to your minds some points in simple anatomy. Entering into the formation of the joints are the articular extremities of the bones, the articular cartilage, the epiphysis, the epiphyseal cartilage, and the lower end of the shaft, sometimes called the metaphysis. According to the attachment of the joint ligaments, there will lie within the joint either the epiphysis alone or the epiphysis plus a portion of the diaphysis—that is a point of great importance in the later pathology. The synovial membrane is supplied by a plentiful anastomosis of blood-vessels, and the supply is most perfect around the reflection of the membrane, and to this complete anastomosis the name of the "circulus vasculosus" has been applied; it is from the circulus vasculosus that the metaphyseal vessels pass into the bone. While there are no lymphatic vessels actually in the synovial membrane itself, there is a plentiful supply in the region of the circulus vasculosus, and a lymphatic connexion is established by means of perivascular vessels with the interior of the underlying bone. The only other point in anatomy to which I must allude is the structure of the synovial membrane. It is a connective tissue structure, lined with a flattened epithelium; beneath the cellular lining there is a condensation of connective tissue which forms really a basement membrane. Beneath this condensed layer there is a zone of loose connective tissue, interspersed with fat cells, and in that tissue there ramifies a complete anastomosis of blood-vessels. In discussing the pathology I shall describe it under the following headings:—(*a*) Development of the primary follicle; (*b*) changes in the synovial membrane; (*c*) changes in the cartilage; (*d*) changes in the blood-vessels; and (*e*) changes in the neighbouring bone. The infection is a blood-borne one, and the original development of the tubercle occurs in the tissue of the vessel wall It is usually of the chronic reticulated variety, and it is rarely that one finds it undergoing caseation As it enlarges it develops into a typical follicle, and giant cells appear early, as in bone tubercle the giant cells are specially distinguished by their size and by the enormous number of nuclei which some of them contain *Secondary to the development of this primary tubercle various sequelæ may occur* 1 The tubercle may spread rapidly over the synovial membrane In such a contingency it is probably of the acute type and it constitutes the miliary form of synovial tubercle. 2 The tubercle may extend generally over the synovial membrane, but it remains chronic, and the synovial membrane undergoes a fibrotic change 3 The tubercle may become general, but in the interspaces between the tubercle there originates a quantity of granulation tissue, which gives to the synovial membrane an œdematous and velvety appearance the granulating form of synovial tubercle 4 The tubercle may remain localised, but the synovial membrane undergoes a fibrosis and is converted into a layer of dense connective tissue And, pathologically speaking, these four possible sequelæ constitute the governing factors in the classification of the varieties of joint tuberculosis —

an [illegible]

de [illegible]

the blood vessels, in the neighbouring bone and the overlying soft parts The changes in the articular cartilage are of two possible varieties, a *perichondral affection* or a *sub chondral affection* The *perichondral change* is the result of the extension over the surface of the cartilage of a diseased synovial membrane, the covered cartilage becomes degenerated, worm eaten and eroded—a perichondral ulceration The covered cartilage undergoes a myxœdematous degeneration and later a true fibrillation The subchondral affection is quite another thing The tuberculous disease extends inwards between the articular cartilage and the underlying bone lifting off the cartilage in large flakes or as a single composite mass I have alluded to the endarteritis which follows the development of tubercle in bones, and an exactly similar condition occurs in tubercle of joints When the endarteritis affects the metaphyseal vessels most important changes ensue, and these I shall speak of under the changes which occur in the neighbouring bones When the vessels entering the bone from the overlying joint become thickened the narrow area which they supply becomes altered It undergoes a fibro myxomatous degeneration, and by doing so becomes especially susceptible to an infection by tubercle Now it depends upon the anatomical relation of the part *whether the entering vessels supply the metaphysis or the* epiphysis and such is the explanation of why in some instances the metaphysis is especially liable to infection, in other cases the epiphysis is the situation of choice Change in the soft parts need not detain us, they are the changes which are spoken of as white swelling or gelatinous degeneration Their pathological explanation is an increased deposit of fat in the parts and a certain degree of œdema —Professor F M CAIRD said that what struck him forcibly was the *extraordinary appearance presented by the blood* vessels, they were so remarkably like syphilitic vessels —Mr HAROLD J STILES said that the treatment of tuberculous bone and joint disease was a very wide question and that it must not be looked upon from the narrow point of view of the specialist or orthopædist In Scotland there were only three large children's hospitals for treating these cases In the in patients' departments of these there were not a sufficient number of beds to enable these cases to be taken in and treated by conservative means Consequently chronic cases from long distances had to be admitted and treated in the speediest possible way The cases which belonged to Edinburgh were treated by some form of light splint which could be removed and massage employed It was a very different matter, however, when one had to deal with advanced cases which arrived at the Children's Hospital from all parts of Scotland These were the kind of cases which Mr Stiles had to treat and it was the least satisfactory He had been accused of applying radical treatment to cases which might have been treated otherwise There was *no large hospital in Scotland* where these cases might be treated conservatively Under present conditions there was no use in taking in a case where the head of the femur was more or less destroyed or where there was a large abscess down the thigh, it was equally useless to send them home untreated They had to do their best. He had no hesitation in saying that the best indeed the only, treatment in order to save the limb and often the life of the child was a radical operation—i.e., complete removal, there was no use opening abscesses or scraping sinuses, partial operations did more harm than good. Another point was the great improvement in the health of the child after the radical operation There was a form of chronic poisoning which gave rise to the anæmic pasty look and also to other symptoms in the child, all these disappeared after the radical operation All that one asked was that the case should be sent before sinuses had developed, and if this were done a radical aseptic operation resulted in a cure The ultimate result very largely depended on the amount of disease and the extent of the operation but it also depended to a large extent on the care which was spent on the after-treatment As regarded the splint, Mr Fraser had pointed out the disadvantage of plaster, but Mr Stiles wanted to point out the advantages If the patient had to be sent far from a doctor the best way to keep the limb at rest was to apply plaster One could not expect the mother to *remove* [illegible] nb, *and if she* did, mo [illegible] It would be a great [illegible] spital to send these patients to It was to be hoped that a fair proportion of the money which the Chancellor of the Exchequer was going to devote to the treatment of tuberculosis would be spent in checking bovine tuberculosis and not in building sanatoriums —Mr A G MILLER said that Mr. Fraser referred to the large proportion of cases in which the bovine strain was present That was not the experience in other places, in a recent French journal it was recorded that of 60 cases examined no bovine type was found This was perhaps due to the fact that the milk was always boiled in France —Mr J W DOWDEN said that it was interesting to find from a doctor in China and from another in Labrador that tubercle of the bones and joints was exceedingly common, although milk was not drunk, that cervical gland tuberculosis was very rare, and when bone and joint disease did occur it was more [illegible] WATSON [illegible] so much [illegible] but as regarded rheumatoid arthritis He had no doubt as to the profound importance of the vessels in relation to the joints as being perhaps the primary factor in developing the latter disease Recently Mr McKendrick had examined 150 [illegible]

alluded to environment as a causal factor in tuberculosis —The PRESIDENT said that the difficulties of treating tuberculosis were quite as great in an adult as in a children's hospital not so much with the immediate but with the after treatment He advocated the institution of a surgical *tuberculosis convalescent hospital* a place which would correspond to the Victoria Consumptive Hospital He claimed that more distress inability to work, and far more pain and suffering were brought about by surgical tubercle than by medical tubercle If a case of excision of the elbow joint is sent out three or four weeks after operation systematic movements could not be carried out the patient *returned to his dirty,* ill ventilated home and the case had no chance of cure If such an institution were erected it would *not be costly,* open air sheds being the chief requirement This would leave the infirmary free for other cases and would admit of patients who required prolonged treatment and nursing obtaining it It was a duty which they owed to the community and it would lighten enormously the responsibility and labours of infirmary surgeons In such an institution each patient would remain for months and have a fair chance of recovery, which at present a large proportion have not He thought that they should agitate and should urge that the first and most important thing wanted was such a con*valescent surgical* tuberculosis home Mr A A SCOT SKIRVING endorsing what the President had said called attention to there being only two in this country—one near Liverpool and the other in the south of England In these the children suffering from tuberculosis of the joints and bones spent practically their whole day on the sands and the whole nights on the balconies close to the sea. It was a wonderful sight to see children with joint disease, spine disease, glands, &c., all being drawn on donkey carriages, some able to drive themselves, some led by relatives. At Berck-sur-Mer, near Boulogne, there were five such institutions, three with 1000 beds each and two with 2000 beds each.—Mr. **FRASER** briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Polycythæmia.—Early Tabes Dorsalis.—Foot and Mouth Disease in Man: Aphthous Fever.

A MEETING of this section was held on Jan. 31st, Dr. J. F. O'CARROLL, the President, being in the chair.

The **PRESIDENT** showed a man, aged 57, the subject of Polycythæmia. On admission to the Richmond Hospital on Nov. 28th, 1912, he was wandering slightly in mind, was very short of breath, and had the deep purple colour of a very ripe plum. The cyanosis was present over the body, though to a less degree than in the face and neck; there was a trace of albumin in the urine, and there was a moderate effusion in the right pleural cavity. But for his extraordinary assurance that he was quite well, he looked as if he had not an hour to live. About 40 ounces of clear fluid were withdrawn from the right pleura, and he was kept under almost continuous inhalation of oxygen. Next day 10 ounces of blood were withdrawn and the oxygen was continued. On Dec. 2nd a blood count showed 7,500,000 red cells per c.mm. with hæmoglobin 105 per cent. Ten ounces of hypertonic saline solution were injected into the pectoral region, and the oxygen was continued. He was again wandering in mind and unconscious of his surroundings. On Dec. 4th he was again bled to the amount of 10 ounces, oxygen being continued. Next day a little over 40 ounces of clear fluid were taken from the right pleural cavity. A blood count gave 3,800,000 red and 7000 white cells, and hæmoglobin about normal. No abnormal forms were found. He was quite reasonable, and apparently comfortable. On Dec. 7th oxygen was discontinued, and 36 hours later a blood count gave about 7,000,000 red cells. Thirty-five ounces of fluid were withdrawn from the right side of the chest. He was again oxygenated for three days, and the red cells fell to 3,500,000 On Dec. 13th 50 ounces of fluid were taken from the right pleura. On Dec. 16th a blood count gave 7,450,000 red cells, on the 19th 9,250,000, on the 31st 6,250,000, on Jan. 15th, 1913, 5,500,000, and on the 22nd 6,500,000. An examination of the specific gravity of the blood showed that it was distinctly above normal. On Jan. 16th an X ray examination showed apparent dilatation of the aortic arch, appreciable both to right and left of sternum. There was no abnormality of the pupils, no aphonia, no tracheal tugging, no pain, no disparity in the radial pulses, and no sign of undue rigidity of the arteries.—Dr. T. GILLMAN MOORHEAD said he was struck with the variation in the number of red cells in proportion to want of oxygen. His experience in cases of chronic heart disease was that the number of red cells was greatly increased. He did not regard polycythæmia as any explanation of the symptoms, but was inclined to look on it as itself merely a symptom.—Dr. J. J. O'KELLY and Dr. W. M. CROFTON also spoke.

Dr. **MOORHEAD** showed a typical case of Tabes Dorsalis occurring in early life in a young woman. Shortly after admission to hospital Wassermann's test was fully positive. Salvarsan was administered, and since then the Wassermann had been negative; but he could observe no improvement in the symptoms. Some girdle pain was complained of since the injection. He invited suggestions as to the advisability of further injections of "606." A careful examination failed to produce any evidence of acquired specific disease, and there was no congenital history.—Dr. O'KELLY said that he had not seen any bad results from the repeated use of salvarsan in cases of locomotor ataxia, provided it was given in small doses. He thought there was no difficulty whatever in doses of 0·1 grm. Girdle pains were frequently found after the administration of salvarsan.—Dr. CROFTON referred to a case of keratitis in which spinal symptoms developed after the second dose of "606," but cleared up on the third dose being given.—The PRESIDENT asked if anyone present had experience of intravenous injections of mercury on the same lines as salvarsan.

Dr. C. M. O'BRIEN related the history of a veterinary inspector who while in discharge of his duty was bitten by a suspected sheep on the finger and himself contracted foot and mouth disease. The patient was seen first a month after infection, complaining of malaise for a day or two previously. On examination the fingers and dorsal aspect of both hands were markedly swollen and covered with a dull reddish, raised rash, extending to an inch above both wrists. On close examination vesicles in process of formation were observable here and there over the surface of the rash, especially between the fingers and round the nails. Itching was complained of. On removing the dressing from the injured finger the wound gaped, but no pus exuded even on making considerable pressure. There was no perceptible involvement of the lymphatic glands. The throat was congested, with a few vesicles on the fauces. There were vesicles on the inside of the lips, gums, and side of tongue. The latter was swollen and somewhat tender. Speech, deglutition, and mastication were painful. Saliva copious. Temperature 100° F., and never exceeded this. Urine normal; internal organs healthy; reflexes normal. Next day all the symptoms increased, saliva trickled from the mouth, and a rash appeared on the dorsal aspects of both feet, similar to that on the hands, stopping short above both ankles. Ruptured vesicles on fauces now gave rise to small shallow ulcers with dark red base. Temperature 99·5°. Sir Charles A. Cameron and Sir Thomas Myles saw the case in consultation with Dr. O'Brien. The patient made an uninterrupted recovery, and, although not quite up to normal standard of physical energy, he resumed duty within two months. Dr. O'Brien in his paper dealt very fully with the literature of foot and mouth disease in man from the first recorded case in 1695 down to the present.—Professor METTAM said that the possibility of infection in man was well known for the past couple of hundred years. The first authentic case of foot and mouth disease occurring in man was recorded about the middle of the eighteenth century, and since then from time to time similar cases had been reported. The incidence of the disease was much greater on the continent than in these islands, and it was most formidable in Russia and France. In 1880 there was a large outbreak amongst persons in Dover who had consumed the milk of cows suffering from foot and mouth disease, and at the time it was noticed that the incidence of the disease was greater amongst those who had used the cream. No observer had yet succeeded in isolating the germ that gave rise to foot and mouth disease, but that it was of a very virulent nature was certain, since a 300th part of a c.c. of the pus taken from a vesicle was capable of setting up a lesion in cattle.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Feb. 6th, Mr. Robert Jones, the President, being in the chair.—Mr. F. A. G. Jeans read a note on One of the Functions of the Cæcum. He had removed the cæcum in rabbits, with the result that fluid fæces were passed instead of the usual hard motions. The practical application deduced was that rectal salines should be large in quantity, as relatively more fluid was absorbed from the right half of the colon than from the left. In bad cases of peritonitis fluid might be injected with advantage directly into the cæcum or through the stump of the appendix.—Mr. F. T. Paul did not think the appendix could be used in cases where it had been found gangrenous, but tubes might be inserted directly into the large bowel.—Mr. W. Thelwall Thomas thought saline injections might be given through a rubber tube fixed in an appendix stump and would so obviate one of the difficulties of rectal injection which had the disadvantage of requiring the patient to be propped up.—Dr. Hugh T. Shaw thought the appendix and cæcum might, from the relative amount of lymphoid tissue they contained, have a protective function as well as absorptive.—Mr. Jeans replied.—Mr. A. Stookes read a note on Puerperal Mortality in Liverpool. The puerperal mortality in Liverpool had for years been lower than the average of England and Wales, in spite of the fact that there was so large a poor population having a grave general mortality. Quoting the statistics of the medical officer of health in 1911, 74 per cent of all births in Liverpool were attended by women with a mortality from sepsis of 0 59 per 1000 births, 26 per cent of births were attended by doctors with a mortality from sepsis of 1 8 per 1000 births In the past six years doctors cases were diminished in number and during that time their sepsis mortality was nearly twice as great as many cases attended by midwives In Liverpool there had been for nearly 50 years an active training school for midwives so that Liverpool had trained midwives long before the Midwives Act Mr Stookes concluded that where midwives were well trained worked under supervision and with skilled help to fall back upon they did the work on the whole better than a badly paid general medical practitioner who was busy with other cases often septic in nature —Dr A A Mussen (assistant medical officer of health of Liverpool) said the satisfactory state of the Liverpool puerperal mortality had been largely due to the Liverpool Ladies Charity, which had trained midwives, so that while England and Wales had some 20 per cent of the women trained and certificated, Liverpool had only 20 per cent untrained Practically all cases were now attended by women who possessed a certificate There had only been one outbreak of puerperal fever in Liverpool in the practice of any one midwife since the health department undertook their supervision Cases occurred usually as single cases a few in groups of two Each midwife was interviewed on the notification of a septic case and her methods inquired into —Dr H Harvey suggested that practically all cases in which doctors were attending were instrumental cases and this was the opinion of several others who took part in the discussion —Dr R J M Buchanan read a paper on Tumours of the Spinal Cord and described with lantern slides four cases where the tumour was psammoma sarcoma hydatid and cancer secondary to carcinoma uteri which had been removed three years previously Dr Buchanan appealed for early operation in such cases and showed how in his cases the tumour was accurately located and had been easily removed the results being most satisfactory —Mr D Douglas Crawford described two successful cases and agreed that operation should be done if only for the relief of root-pain —Dr W B Warrington had seen nine or ten cases where the lesion had been successfully located Tumours with no pain might give rise to difficulty The nerves which convey sensations of temperature and pain had a rather long path in the cord before crossing and so might give rise to some difficulty in locating a lesion He thought operation was often attended by brilliant results —Mr Thelwall Thomas thought it a pity that cases should be allowed to go on so long before a diagnosis was made and something done Improvement would naturally not follow when the cord had been long compressed He said there was more danger in exploring the spinal canal than in exploring any other cavity of the body —Dr Buchanan replied

Leeds and West Riding Medico Chirurgical Society —A meeting of this society was held on Feb 14th Dr Dobson the President being in the chair —Mr H Collinson read a paper on The Importance of Early Diagnosis and Treatment in Acute Perforated Duodenal Ulcer After dealing with the symptoms and differential diagnosis of the condition he pointed out that mortality in operated cases was directly proportionate to the number of hours which had elapsed between the occurrence of perforation and operation In 27 cases upon which he had operated during the last three years the mortality was 41 per cent Of these, ten were operated on within 12 hours with a mortality of 10 per cent ten cases operated on in the second 12 hours gave a mortality of 40 per cent and in seven operated on after 24 hours had elapsed the mortality rate was 86 per cent A number of points in the operative technique were discussed and he pointed out that the performance of an immediate gastro enterostomy was not necessary for the recovery of the patient and consequently should be reserved for those cases in which operation was undertaken very soon after the perforation had occurred —Dr T Wardrop Griffith showed a case of Disseminated Sclerosis *of which the first symptom noticed in October* 1912 was squint with diplopia This which was due to paresis of the abducens nerve had, to a great extent passed off Marked weakness of one arm and then of the opposite leg soon came on in succession but had undergone a striking improvement There was no intention tremor or staccato speech, but though there had been great improvement the diagnosis was confidently affirmed on the great increase of the knee jerk, on the Babinski phenomenon, on the presence of slight nystagmus on lateral movement and on incipient atrophy of the optic nerve —Dr C W Vining showed a case of Malignant Growth causing pressure upon the main bronchus of the left lung The patient was a male aged 54 years who had suffered with cough and breathlessness for two years and who had had hemoptysis on two occasions The physical signs were greatly diminished expansion with reduced air entry over the whole of the left chest X rays showed no evidence of growth or aneurysm There were no tubercle bacilli in the sputum —Cases were also shown by Mr L R Braithwaite Dr M J Stewart Mr E W Bain, Mr J F Dobson Dr A Bronner Mr L A Rowden Dr C Oldfield Mr R Lawford Knaggs Mr Alexander Sharp Dr R A Veale and Dr G W Watson

Nottingham Medico Chirurgical Society —A meeting of this society was held on Jan 22nd Mr W G Laws the President being in the chair —In opening a discussion on the Medical Aspect of Education Dr L W Marshall said that the aim of teachers should be to produce first physical fitness and then mental culture in their scholars The various parts of the body developed at different periods and the attention of teachers should be drawn to these periods Speaking generally private tuition was bad It was most important that the preparatory schools should be good and such as gave great attention to the early development of the body Only children were greatly to be pitied The kindergarten system was the best for the ages of 4 to 7 years From the seventh to the ninth year neuroses were developed and should be carefully watched At this period the teeth were changing and sleep was apt to be affected After the ninth year the cardio vascular system developed enormously From the seventh to ninth years discipline should be enforced, mental pressure might be developed from *the ninth to the thirteenth* years This was a period when the ' will power was developing and just preceded the commencement of the sexual development at the age of 13 years —Dr Sarah Gray laid great stress on eliminating all physical defects She paid great attention to the nervous child—i e one of exalted sensibility The objects of the teacher should be to (1) make the child a healthy animal, (2) avoid stimulation in every way (3) provide for ample sleep, (4) allow the child a definite amount of leisure time daily to itself—i e to allow it to amuse itself, and lastly not to overwork the child—especially between the years of 9 and 13 —The discussion was continued by Dr S E Gill Dr J S Bolton and Dr W Hunter

---

Dr Ranking Memorial Tunbridge Wells —The endowment of a bed in the local general hospital has been decided upon as the form of the memorial at Tunbridge Wells to Dr John E Ranking who was killed in a motor accident at Bexhill in September last Both rich and poor have subscribed to the fund the donations ranging from one farthing to 100 guineas Just over £200 are still required to raise the £1000 which is needed, and the fund will remain open until April

Taunton and Somerset Hospital —The annual meeting of the *subscribers to the Taunton* and Somerset Hospital was recently held under the presidency of the Hon H B Portman The medical report was satisfactory and the financial statement showed that during 1912 in addition to the investment of £13 726 bequeathed to the hospital by the late Mr J Cook the committee had also invested £1059 being the surplus of income over expenditure This satisfactory result is due to the exceptional amount which has been received from bequests and special donations especially the sums of £1000 each for the endowment of two beds presented by the *Hon Mrs* Portman and the Hon H B Portman respectively in memory of the late president the Hon E W B Portman During the past year the honorary medical staff had been increased by the appointment of Mr A T H Iles M R C S Eng, L R C P Lond, as medical officer in charge of the newly established [illegible] al department

Reviews and Notices of Books.

A Manual of Immunity for Students and Practitioners. By ELIZABETH T. FRASER, M.D. Glasg., late Assistant Bacteriologist Glasgow Royal Infirmary; Beit Research Fellow. Glasgow: James Maclehose and Sons. 1912. Pp. 199. Price 5*s.* net.

THIS small volume is a very successful attempt to place the fundamental facts of immunity and their application to modern medical practice before the practitioner and student of medicine. It might also be read with profit and pleasure by any scientifically educated layman interested in medical progress, for the author's style is, at least, less arid than that usual in scientific text-books. As she remarks, it is obvious that the physician can no longer be a "mildly interested looker on" while others apply to practical medicine methods of diagnosis and treatment which are based on the study of immunity, or "he will be forced into the position of a passive transmitter of ideas which are entirely beyond his grasp." The author appears to think that what she describes as the "almost wanton" introduction of new terms has scared the practitioner from a study of the subject. Naturally, therefore, an attempt is made in this book to clear the subject of technical terms. It is, however, a difficult matter to make more than an apparent clearance, and is largely in this case effected by relegating such terms to a glossary at the end of the book.

Though the work is not technically divided into two parts, the subject is treated in two sections. The first deals with immunity in general, viewed from a threefold standpoint as it relates respectively to the body fluids, the body cells, and the varying resistance of the micro-organism concerned in an infection. This portion is excellent, the facts are well arranged, and the fundamental ideas are not lost in a cloud of detailed observations. The result is a well-balanced account of the importance of the various factors of influence in the production of immunity and of the share which the various schools of bacteriology have taken in their elucidation. The second portion, occupying about half the book, deals with immunity reactions applied to therapeutic and diagnostic ends. This portion is, perhaps, scarcely so satisfactory as the earlier part of the book, a fact which probably arises from the nature of the subject rather than from the method of treatment. The necessary compression of statement renders it impossible to give the clinical basis on which belief in the therapeutic or diagnostic efficiency of the methods is founded. As the author says in reference to the value of vaccines in treatment, this has to be based on individual clinical impressions and not on any scientific data. The view of the desirability of preventive inoculation with antidiphtheritic serum is more strongly held than is usual in this country, and the recommendations of the French Academy of Medicine are quoted in support. In the section on reactions used for diagnostic purposes the complement-fixation test and its derivative, the Wassermann reaction, naturally occupy a prominent position. The technique devised by Boas is strongly recommended for the Wassermann reaction, though it is certainly not a simplification.

The book is not a laboratory manual, and therefore technical descriptions of methods are not always complete; there is an omission of any reference to agglutination in relation to Mediterranean fever. Chapters on anaphylaxis and chemotherapy, together with a statement of Ehrlich's side-chain theory, complete the work. It is certainly a book to be recommended to the practitioner and is presented in a pleasant and well-printed form.

Die Störungen der Sehfunktionen. Von Dr. W. LOHMANN. Leipzig: F. C. W. Vogel. 1912. Pp. 206. Price, paper, 10 marks; bound, 11.50 marks.

THE need for an up-to-date introduction to the study of what is ambiguously termed physiological optics has long been felt by those whose enthusiasm carries them beyond the everyday routine of ophthalmology and neurology. The need has been met to some extent in this country in a recent book by Mr. Major Greenwood, jun.

The present work covers somewhat similar ground, but has the advantage of giving recent references to literature, so that the study may be extended and amplified if desired. Hitherto information has had to be sought in vast treatises like Helmholtz's Physiological Optics or Nagel's encyclopædic so-called "handbook" of physiology. In both the exposition was intended for the pure scientist: there was much that was beyond the requirements or possible scope of the clinician, and there was little or no reference to pathological states. Dr. Lohmann throughout deals with the subject in direct relationship to diseased conditions. After a preliminary section on the physical, physiological, and psychological aspects of vision he considers blindness in its various relations, chiefly psychological. Visual defects due to refractive errors are next reviewed briefly, and such conditions as metamorphopsia and the entoptic appreciation of opacities of the media. The next section treats of the abnormalities of central and peripheral vision with their physiological bases. A valuable chapter discusses the anomalies of adaptation and the light sense, anomalies which often do not receive due recognition from ophthalmologists. Retinal adaptation and the peculiarities of vision in a dull light are adequately discussed, and von Kries and Hering's theoretical considerations reviewed. Colour vision occupies two chapters, devoted respectively to congenital and acquired defects. The succeeding chapters deal with chromatopsias, "colour hearing," binocular vision, defects from lesions of the visual paths and centres, and subjective optical phenomena.

There is little new in the book, but as an introduction to the more recondite problems of vision it can be warmly recommended. It is exceptionally well printed and illustrated.

A Text-book of Obstetrics. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania. Seventh edition. With 900 illustrations, 50 in colours. London: W. B. Saunders Company. 1912. Pp. 1013. Price 21*s.* net.

IF but little need be said about a text-book which has reached its seventh edition it is none the less fair, from time to time, to notice the various steps in its revision which enable it to continue to hold its own. A change has been made, for example, in the arrangement of the chapters of this manual; the physiology of the process of generation precedes the pathology, with the exception that sterility is considered in direct connexion with normal conception, while malpresentations are naturally included under the head of the mechanism of labour.

The author considers that it is right to include the diseases of women and their treatment as a necessary part of obstetrics, and this plan has been continued in this edition. The contention that the consequences of child-bearing constitute the majority of the diseases of women is, of course, quite a sound one, but at the same time it is a question whether an attempt to combine the two subjects in one volume is not a mistake, and apt to lead to an imperfect account of both. However, in the present work the author has accomplished his purpose well, and, as he points out, the master of a modern maternity service is the only specialist in command of sufficient clinical material to be a qualified expert. It is interesting to learn that some of the best medical schools in America have dispensed with a separate department for teaching diseases of women, and that the rest will probably do the same eventually, to avoid the unnecessary duplication and the imperfection of teaching inevitable, in the opinion of the author, if the two subjects are separated The attitude can only be maintained with difficulty To the inclusion of an article on diseases of the breast in a work devoted primarily to obstetrics there are, in our opinion, many objections Perhaps the practice in America differs, but we imagine very few obstetric physicians in this country ever undertake the treatment of any of the diseases of the breast which are not immediately connected with child bearing Certainly in this country the general surgeon is likely to acquire a much greater experience in diagnosis and treatment in these matters than the obstetrician and gynæcologist

The whole work has been revised and in large part re written The author apparently is not much in favour of pubiotomy, and would limit the operation to cases in which the head is impacted low in the pelvis and in which there is *insuperable obstruction from a contracted outlet, or to* mento-posterior positions of a brow or face with the cervix fully dilated, two classes of cases in which the majority of operators would consider pubiotomy certainly not indicated On the merits or defects of extraperitoneal Cæsarean section Professor Hirst does not apparently express any decided opinion

Though the book contains a great deal of information it remains unequal, thus the section on the treatment of placenta prævia is excellent, while that on the treatment of accidental hæmorrhage is disappointing In the latter condition the author seems to favour treatment by *accouchement force*, and no mention is made of the method of plugging the vagina, nor is there any clear distinction between cases of concealed and those of external accidental hæmorrhage There are a large number of excellent illustrations, of which many are in colours

A Treatise on Tumours BY ARTHUR E HERTZLER, M D, Ph D, Associate Professor of Surgery in the University of Kansas With 538 engravings and 8 plates London J & A Churchill 1912 Pp 725 Price 30*s* net

THIS work is evidently the outcome of a large amount of experience, alike in the clinical study of tumours in their histological examination, and in the teaching of students, and we think that the author has attained his aim, which was, he tells us, to write a book which should provide for the student and the practitioner information both on the clinical and scientific aspect of tumours

In the account of individual tumours and of the nature of tumour growth there is much that is original. Dr Hertzler is inclined to hold that a modification of Thiersch s theory will best explain all the phenomena of the formation of new growths He agrees with Thiersch that the primary change in the formation of a carcinoma is a lessened resistance in the connective tissue which permits the epithelium to proliferate Further, he has observed that the connective tissue in the neighbourhood of a carcinoma contains fewer cells, losing in part its affinity for acid dyes, and therefore he suggests that the lessened acidophilic property of the connective tissue permits the invasion of the basophilic epithelium, or, to express it in another way, invasion of the connective tissue occurs whenever the basic power is excessive or the acidophilic power is reduced The theory is ingenious, but it is doubtful how it will stand the test of *time The parasitic theory* is dismissed with a *somewhat* brief description

The several varieties of tumours are described in order, the tumours composed of simple tissues being taken first. In the account of the osteomas the author has not made it clear that the ivory and the cancellous osteomas have essentially different modes of origin, the ivory exostosis being derived from periosteum, while the cancellous exostosis is formed by the ossification of cartilage Also in the description of the treatment he has not made it clear that it is necessary that the whole of the cartilage covering a cancellous exostosis be removed before the surgeon can guarantee that the osteoma will not return In the account of carcinoma the author describes under the heading of basal celled type the ordinary rodent carcinoma and he appears to think that it was first fully described by Krompecher in 1903 The name he uses is unfortunate, as the author himself remarks, for it is certain that these growths are not derived from the basal cells He goes on to say that "Coenen has particularly expressed the belief that they develop from either the sudoriferous or sebaceous glands," as if this were a new opinion But Coenen's paper did not appear till 1907, and this origin of these tumours had then been cleared up for nearly 30 years The chapter on the general diagnosis of tumours is one of the best in the book, and the remainder of the work consists *of a sound account of the tumours affecting* the several regions of the body The work gives a clear account of tumours, and the practical application of the facts which have been ascertained as to their nature is also clearly set forth

Medical Diseases of Children (London Medical Publications) By T R C WHIPHAM, M A, M D Oxon With 67 illustrations London University of London Press (Henry Frowde and Hodder and Stoughton) 1912. Pp 417 Price 10*s* 6*d*

THIS new work on the medical diseases of children is a plain, straightforward account of the common complaints to which infants and young children are subject It is clear, without specific intimation of the fact in any introduction or preface that Dr Whipham has addressed himself more to the student than to the practitioner For examination purposes this work contains neither too much nor too little information, from the point of view of treatment the details are probably insufficient and certainly far too general The illustrations, which are original and almost, if one may say so, artistic, make an outstanding feature of the book

Inasmuch as the whole subject of the medical diseases of childhood is included in the scope of this work and inasmuch as the total number of pages only amounts to some 400, it is clear that there can be no dallying with the refinements of style and the attractions of controversy The book is businesslike and to the point from start to finish, and for the guidance of inquirers it may be stated that it is of about the same size, and of about the same standard of fulness as Dr Alfred Carter's well known "Elements of Medicine" If there is such a thing as an English school of pædiatrics, this work of Dr Whipham may be said to be thoroughly representative of it As a late secretary, and always an active member of the Children's Section of the Royal Society of Medicine the author records his experiences in these associations on almost every page of his work Whether he has been altogether wise in ignoring so much of the work of French, German, and American writers is another matter We think that the work of Czerny and Finkelstein on the disorders of nutrition deserves to be included in an up to date text book of diseases of children, and we are disappointed to find that the closely allied triad of symptoms, tetany, laryngismus stridulus, and eclampsia have not been grouped together according to the *German method under the common* heading of spasmophilic neuroses The association of these symptoms with rachitis is referred to by Dr Whipham but the important fact that phosphorus has an almost specific influence in the treatment is not mentioned, and doubt is further cast on its efficacy in the treatment of rickets in the more general manifestations of this disease.

In the chapter which deals with scurvy we notice the somewhat remarkable statement that the dangers due to the sterilisation of milk can be obviated by carrying out the process of sterilisation in small bottles, each containing sufficient for one feeding. "In this way the loss of alkaline salts can be reduced to a minimum, and the child be fed on a harmless and efficient food." On p. 197, in reference to the troubles of dentition, it is stated that when there are much redness and swelling a crucial incision over the erupting crown will generally cause an abatement of the symptoms. While thoroughly agreeing with this line of treatment, we cannot help thinking that the steps to be taken in dealing with the eruption of the canines, which usually give the most trouble, are not accurately described by the injunction to make a crucial incision. The crucial incision should, in the opinion of most dentists, be reserved for the molars, and linear incisions made in the case of the single teeth. Again, and with no wish to be hypercritical, we cannot help taking exception to the statement, on p. 125, that measles can be an "*exciting*" cause of tuberculosis; while on p. 339 we are told that enlarged tonsils are a "*reflex*" cause of nocturnal enuresis, which can hardly be true.

Owing to its general accuracy and temperate views this new work on the medical diseases of children is a perfectly safe work to put into the hands of a student.

Psychology: a New System based on the Study of the Fundamental Processes of the Human Mind. By ARTHUR A. LYNCH, M.A., C.E., L.R.C.P. Lond., M.R.C.S. Eng., M.P. In two volumes. London: Stephen Swift and Co. 1912. Pp. 814. Price 21*s.* net.

IT is unusual in these days to envisage the possibility of a science being born or re-born by a Minerva-like parturition in the brain of an individual thinker; and, outside the domain of metaphysics, where by prescriptive right every theoriser may spin a complete speculative web of his own, we hardly expect to find a writer claiming to expound a totally new system in any branch of knowledge. It may therefore be something of a shock to the reader of Mr. Arthur Lynch's "Psychology" to discover from the first pages of the work, and indeed almost from its title, that it purports to present considerations on the science of mind which are "new not only in regard to subsidiary points, but in the enunciation and solution of the basic problem of them all." This is a very large claim, and an author who makes it must expect to have his facts and arguments scrutinised very closely before his conclusions can be adjudged to be at once as new and as true as he represents them to be. It is impossible to pretend that Mr. Lynch's work supports this ordeal very satisfactorily.

The essential feature of his system is the differentiation in the working of the mind of what he terms the fundamental processes, or, as he elsewhere calls them, the non-analysable faculties. This has rather the familiar ring of the system of classification dear to the psychology of an earlier generation; and the sense of familiarity is deepened when we learn that these processes are discovered by "the old methods of mental analysis and introspection," eked out with the help of "elementary physiological facts." Of course, an old method may be put to new and more profitable uses, but it is difficult to see in what respects Mr. Lynch's analysis brings us to any clearer perception of the facts of mind. The fundamental processes which it reveals are, it seems, 12 in number—to wit, immediate presentation, conception of unit, memory, association, agreement, generalisation, feeling of effort, impulse, hedonic sense, sense of negation, conception of time, and conception of space. Now, though the bringing together of these terms as applying to conceptions on the same plane does, indeed, produce a certain sense of strangeness, and though the terms themselves in some instances are new or are old terms taken in unusual meanings, it is tolerably obvious that the aspects of mental activity which they connote belong to the regular stock-in-trade of psychology, and that the novelty which they possess may therefore be no more than verbal.

To decide whether they have any higher value we may turn to the exposition of some one of these fundamental processes. Let us take, for instance, memory: what has Mr. Lynch to teach us concerning this phenomenon? "Let us speak," he says, "of Idea as the image which the mind displays of a past experience, such as a particular sensation. ...... Memory is the Fundamental Process by which the Idea is made known as existing" (p. 28, Vol. I.). Now, if there is in this statement any departure from the current definitions of memory in psychological text-books, it is assuredly in the direction of confusion and inaccuracy. Are we to understand that the idea, taking the term in the peculiar meaning which the author attaches to it, has an existence apart from memory? If so, what is the "fundamental process" by which the mind "displays" it? If, on the other hand, it only comes into being through the operation of memory, how does the gratuitous introduction of this term, with its initial capital, add anything but obscurity to the discussion? It would be easy to multiply from other chapters of the work similar instances of confused thinking and nebulous phraseology, but this may suffice to show the general mode of treatment adopted by the author. If he has a mind to write on psychology, Mr. Lynch would be well advised to cultivate a more rigorous accuracy of thought, a keener spirit of self-criticism, and a simpler style.

Lehrbuch der Haut- und Geschlechts-Krankheiten. Herausgegeben von Professor Dr. ERHARD RIECKE, Leipzig. Zweite vermehrte und verbesserte Auflage, mit 17 Farbentafeln und 307 grossenteils mehrfarbigen Textabbildungen. Jena: Gustav Fischer. 1912. Pp. 756. Price, paper, 16.50 marks; bound, 18 marks.

THIS book, which is edited by Professor Riecke, of Leipzig, has been written by a number of German, Austrian, and Hungarian physicians, each of whom holds a high position in dermatology.

The chapter on what may be called general dermatology has been written by Dr. Gustav Riehl, of Vienna; this deals with the anatomy and physiology of the skin, and contains also an account of the symptomatology. Dr. Salomon Ehrmann, of Vienna, has written the section on acute and chronic eczema; Professor Riecke, of Leipzig, has taken all the scaly eruptions; Professor Bettmann, of Heidelberg, has written the articles on the vesicular and bullous eruptions; Professor Leo von Zum Busch, of Vienna, is responsible for the account of the skin lesions due to disturbances of circulation. Professor Török, of Budapest, has taken the diseases of the sweat glands and of the sebaceous glands, the alopecias, and the other affections of the hairs not due to hyphomycetic fungi. Professor Grouen, of Halle, has dealt with the tuberculous affections of the skin and most of the other granulomata. Professor Tomasczewski, of Berlin, has written on the new growths of the skin; Professor Riecke on ichthyosis and keratoma and similar conditions; and Professor Jesionek, of Giessen, has described the animal and vegetable parasitic affections of the skin. In the section dealing with the venereal diseases, Professor Bruhns, of Charlottenburg, has written the articles on gonorrhœa and soft sore, while the important subject of syphilis has been allotted to Dr. B. Buschke, of Berlin.

It will thus be seen that the editor has succeeded in enlisting the aid of a very distinguished band of writers, and the result is all that might be expected In a work on diseases of the skin the illustrations have probably a greater importance than in a work on any other subject, and in this volume they are above the average There are many coloured plates which are excellent, and in addition many of the illustrations in the text have been printed in colours

---

Tumours of the Jaws By CHARLES LOCKE SCUDDER, M D With 353 illustrations, 6 in colours London and Philadelphia W B Saunders Company 1912 Pp 391 Price 25*s* net

"A BOOK without a smile" would be, perhaps, an appropriate general description of this volume The feature of the work is the illustrations, which are more numerous than the pages, the author having brought together portraits demonstrating the awful ravages and gruesome distortions of the face that ensue when tumours in these regions are not detected and surgically treated in their early stages New growths of the jaws, relatively speaking, are not common, and it is the infrequency of these cases that increases the responsibility of the practitioner

The object of Dr Scudder's monograph is, firstly, to assist the practitioner in determining in a given case what form of new growth is present and what is its best treatment Secondly, to make vivid the picture of each tumour of the jaw by statistical story and by case history, so that the practitioner may recognise the new growths of the jaws in their early stages Epulis, sarcoma of the jaws, benign tumours of the jaws, the odontomata, carcinoma of the jaws, the diagnosis and operative treatment of malignant disease of the upper and lower jaws, tumours of the palate, leontiasis ossea, and, finally, prosthesis are successively dealt with in nine chapters As regards treatment, Dr Scudder considers that the operation should depend largely upon the character of the tumour A mutilating operation should not be done for a relatively benign form of malignant growth On the other hand, a very thorough and much more extensive operation is demanded for the malignant growths than has been practised in the past

The book is well produced, and is the first complete description of the growths of the jaws in American medical literature

LIBRARY TABLE

Another Device By STEPHEN PAGET London, New York, and Toronto Hodder and Stoughton Pp 326 Price 5*s* net —The medical man who has not read "Confessio Medici" has much left to ponder and enjoy And when he has accomplished that there yet remains for him "Another Device" Before he shall have finished that, let us hope that Mr Stephen Paget will be ready with still another treasury of illuminating thoughts, expressed in that terse direct, and startlingly apposite language which, as we said in reviewing the first named book, constituted veritable links binding literature to medicine In this, as in the former volume, the wide range of the author's themes is noteworthy, but here his purview is no longer limited by the horizon of medicine, but includes the wider activities of man, inclusive of woman and child What a delightful cameo he carves of the Right Sort of Girl How aptly she is compared with her predecessor of mid-Victorian days "Fifty years ago she would have been called, by the women of that memorable time, a boisterous and undisciplined child But she was not there fifty years ago, and, if she could have been there, she would not have been what she is here The present state of things is the making of her, it is in every day of her life, every hour of her day" And finally, how adequately he sums her up: "They who know her a little, call her pleasant but superficial; they who know her well, call her a fine character but rather uneven, they who live with her, admire her faith, reverence, self-judgment, and passionate desire to make the right use of her life" And "her little world"—which is all of us, for do we not all know her?—"says that, if she does not marry and have children, it will be a dreadful waste of just the sort of girl who ought to do that" We can feel equally with the author as philosopher in his practical comment on the Influence of Berkeley, as man in the street, in his *reductio ad communia* of Heredity and Life, as artist in his impressions on the First Sight of Rome There are times, it is true, when Mr Paget is hypercritical, as when he says (p 226), talking of style, "there is no style in *As it was in the beginning, is now, and ever shall be, world without end*, but it sounds well in Latin, *Sicut erat in principio, et nunc, et semper, et in sæcula sæculorum*" Many, on the contrary, must feel that the English loses nothing of dignity or beauty by comparison with its Latin original There is more serious and pertinent matter in such essays as Hospital Life, the Doctor's Opponents, the Genius of Pasteur, and the Revival of Phrenology, but treated always in the lighter rippling vein, which confers life and movement on the current of thought without obscuring its rocky bed below We said, when reviewing Mr Paget's earlier work, that the author was a notable maker of phrases In the present book, speaking of a holiday, he says "If it is more than eight weeks it is not a holiday. It is a house in the country" We also said that he knew his Juvenal and his Shakespeare, to which we may now add that greatest book of all, his Human Nature

Fortschritte der Naturwissenschaftlichen Forschung Herausgegeben von Professor Dr E ABDERHALDEN, Direktor des Physiologischen Institutes der Universitat, Halle a S Funfter und Sechster Bande Berlin, Wien. Urban und Schwarzenberger 1912 Price, each Band, 15 marks, bound, 17 marks —The subjects treated in the fifth volume of the "Progress of Natural Science" are the Origin of Sex, by Dr Kammerer, of Vienna, the Telegraphon, by Dr Eichhorn, of Zurich, the Foods Required by Adults in their Relation to Bodily Work, by Professor R Tigerstedt, of Helsingfors, and a paper on Transplantation, by Dr G Axhausen, of Berlin The articles which make up the sixth volume include such subjects as the Present Position of Nautical Science, by Professor W Halbfass, of Jena, Geomorphology, by Dr Ruhl, of Berlin, Optic Sensibilisers in the Animal and Vegetable Kingdom, by Dr Hausmann, of Vienna, and the Results of Radio active Investigation, by Dr Hahn and Dr Meitner, of Berlin There are only two contributions that will appeal directly to medical men—one on Functional Psychoses, by Dr O Bumke, of Freiburg i B, and the other on Regeneration and Allied Subjects, by Professor Barfurth, of Rostock, a subject which has special attraction for medical men who take an interest in pathological problems of regeneration largely treated from the point of view of the comparative anatomist To profit fully from Professor Barfurth's exceedingly interesting and comprehensive paper the reader must have a good knowledge of invertebrate and vertebrate structure and embryology The references to the literature alone run into nearly 20 pages

Concerning Conscience By H JEFFS London James Clarke and Co 1912 Pp 278 Price 3*s* 6*d* net —This book might very well have as its subtitle "Lay Sermons" and, indeed, we gather from the preface that Mr Jeffs is a lay preacher among his other occupations He writes in plain, simple language and with a manifest intention to be scrupulously fair, qualities which should ensure him a respectful hearing, even were his matter of a far lower quality but that pancreatic rennin is a ferment entirely different and distinct from gastric rennin. In both processes calcium salts may be replaced by salts of barium, strontium, or magnesium. The author puts forward a hypothesis as to proteolytic ferments which coagulate milk, which is fully stated in the original text.—Fatty Acid Metabolism in the Liver: II., The Relation of the Fatty Acids in the Food of Plaice to those in their Livers and Myotomes, by V. H. Mottram. Fatty acids of marine vertebrates have a very high iodine value, but they are not characteristic of vertebrates, for those of the mussel are also of high iodine value.—The Ferments of the Pancreas: I. Generation of Trypsin from Trypsinogen by Enterokinase, by John Mellanby and V. J. Worley. The following are some of the authors' observations:—The length of time taken by the activation process is a function of the amount of enterokinase added. Reaction proceeds most rapidly in neutral solution, is delayed by alkali, and stopped by acid. Proteins delay the activation process.—Broncho-dilator Nerves, by W. E. Dixon and Fred. Ransom. It is known that the vagus contains both broncho-dilator and broncho-constrictor fibres. The authors found that the bronchial muscles are supplied by powerful broncho-dilator nerves of sympathetic origin. The fibres proceed mainly through the rami of the first, second, and third dorsal nerves to the ganglion stellatum, and proceed to the lungs with the cardiac accelerators. A variable number of fibres pass down the cervical sympathetic, and these, like the others, have their cells in the G. stellatum. Adrenalin in an animal showing bronchial tonus causes active temporary dilatation, atropine causes passive permanent dilatation.—The Proceedings of the Physiological Society for Oct. 19th, 1912, include the following: F. W. Edridge-Green: Simultaneous Colour Contrast, XIX. E. M. Tribe: Effect of Adrenalin on the Pulmonary Circulation (preliminary communication), XX. J. B. S. Haldane: The Dissociation of Oxyhæmoglobin in Human Blood during Partial CO Poisoning, XXII. Nov. 23rd, 1912.—Ida Smedley: The Biochemical Synthesis of Fatty Acids from Carbohydrate, XXV. H. H. Dale: The Anaphylactic Reaction of Plain Muscle in the Guinea-pig, XXVII. H. Hartridge: The Sensation of Yellow, XXIX. W. M. Bayliss: A Simple "Frictionless" Tracing Point, XXXI. W. Burridge: Some Points on Excitation and Contraction in Muscle, XXXII.

Parasitology. Edited by G. H. F. NUTTALL, F.R.S., and A. E. SHIPLEY, F.R.S.; assisted by EDWARD HINDLE, Ph.D. Vol. V., No. 4. January, 1913. London: C. F. Clay, Cambridge University Press. Price 10*s*. Yearly subscription £1 10*s*.—The Fixation of Rabies Virus in the Monkey (Macacus rhesus), with a Study of the Appearance of Negri Bodies in the Different Passages, by H. W. Acton and W. F. Harvey, contains strong evidence in support of the view, advocated by these investigators, that the Negri bodies of rabies do not represent any parasite, but are the result of a development round nucleolar fragments in the cytoplasm of the ganglion cells. The size of the Negri bodies was found to steadily diminish on passage through monkeys, until they became almost ultra-microscopic. At first they were large and, with Mallory's iron hæmatoxylin and Bordeaux red, stained brown to black, but by the sixth passage they stained wholly black, being identical in staining reactions with the nucleoli. At the seventh passage, together with the development of the paralytic form of rabies, there was a very decided drop in the number of Negri bodies present, and this fall continued through the following passages. It seems, therefore, that the Negri body as found in the ganglion cell tends to disappear altogether from this region with the attainment of fixity of the virus. Bullocks injected with street virus showed large Negri bodies, whereas those injected with fixed virus showed none at all.—The Life-History of Dermacentor Variabilis, by Seymour Hadwen, consists of notes and observations on the life-cycle of this tick in Manitoba. The ticks were raised on rabbits and were found to drop off their host after each stage, the whole cycle from the egg to the adult occupying about 210 days.—New Trematode Parasites from Fishes of the English Channel, by William Nicoll, contains the descriptions of four new species obtained from the fishes of the English Channel at Plymouth. One of these new species, Podocotyle syngnathi, was found in pipe-fishes. The remaining three species—Lepidauchen stenostoma, Hemipera ovocaudata, and Derogenoides ovacutus—are each made the type of a new genus. The author concludes with a discussion of the affinities of the last two genera.—Trypanosomes Found in a Cow in England, by Alfred C. Coles, contains the description of a trypanosome found in the blood circulation of a cow from Dorset. Only two parasites were seen, but from their description it seems probable that this trypanosome is the same (apparently non-pathogenic) species that has been described from many other parts of the world.—In Memoriam: Wilhelm Dönitz, by G. H. F. Nuttall, is a short account of the life of this distinguished investigator. The article contains a complete list of his publications, including works on general zoology, anatomy, entomology, parasitology, medicine and surgery, pathology, bacteriology, and immunity. This remarkable versatility was also accompanied by very able administrative capacities, these being recognised by his appointment to the directorship of the Institute for Infectious Diseases at Berlin.—The Herter Lectures, by G. H. F. Nuttall, include two of the lectures delivered by the author at Johns Hopkins University, U.S.A., in October, 1912. The first lecture, on Spirochætosis, not only summarises the most important recent advances in our knowledge of this subject, but also contains many interesting original notes and observations. The author emphasises the fact that the various specific names given to the spirochætæ causing relapsing fever in man are merely convenient expressions in order to distinguish races or strains of different origin. They cannot be regarded as valid names, for virulence and immunity reactions are not adequate tests of specificity. In the second lecture, on Trypanosomiasis, the author succeeds in presenting a summary of the mode of infection of trypanosomiasis in both man and animals, and also an account of the powers of adaptation shown by trypanosomes.—Nuttallia und Piroplasma bei der Piroplasmose der Einhufer in Transkaukasien, by Dschunkowsky and Luhs, contains a description—in German—of the piroplasmosis of horses and mules in Transcaucasia. The horses were found to be infected with both Nuttallia equi and Piroplasma caballi. In addition, the authors noticed the presence of Nuttallia in a mule, and were able to infect both horses and donkeys by injections of its blood. Also a new species of Nuttallia—N. asini—is described from the blood of donkeys, in which animal it produces a somewhat chronic form of piroplasmosis.

Jahreskurse für ärztliche Fortbildung. January, 1913. Munich: Lehmann. Price 18*s*. a year.—In this number of the Annual Course of Post-graduate Study, Professor Pick contributes an article on the metabolism of proteins in the animal body, and Professor Lubarsch discusses the limitations of pathological anatomy and histology and its recent problems. Professor Pick gives a valuable account of the behaviour of albumin after injection into the blood stream, when it may produce the phenomena of anaphylaxis, and then discusses its digestion by the ferments pepsin, trypsin, and erepsin. Pepsin splits off from the albumin molecule albumoses, peptone, and a residue, probably polypeptide, which does not give the biuret reaction Trypsin resolves the greater part of the albumin or peptones into amino acids, but there is a certain residue of unaltered "antipeptone" This is broken down, like other peptones, into amino acids by the erepsin Bacteria resolve the amino acids into still simpler products In patients with cancer of the stomach there is often an abnormal ferment in the gastric juice which splits the polypeptide glycyl tryptophane into its constituents Professor Lubarsch writes upon the signs of death having actually taken place, and then discusses the post-mortem signs of those diseases in which the pathological findings are not very distinctive, with special reference to the infective fevers, acute hæmorrhagic processes, and inflammatory conditions of the eye The histological distinction between the granulomata and the recognition of the early stages of malignant disease also come up for review, but the descriptions do not include anything very novel The statistics of tuberculosis at necropsy are also given for Düsseldorf as follows —

Deaths from Tuberculosis

1908	437 = 1 57	*per 1000*	*inhabitants, and*	10 75 %	*of total*	*deaths*
1909	485 = 1 48	,	,,	10 36	,,	,,
1910	507 = 1 44	,,	,,	11 7	,,	,,

Tuberculous changes were found in 46 2 per cent of all post mortems in 1910, whereof the mischief was active in 22 8 per cent and quiescent in 23 4 per cent In children the figures were higher, tuberculosis, recent or old, was found in more than half of all cases coming to necropsy, the exact ratio being 60 9 per cent in 1908 62 1 per cent in 1909, and 59 3 per cent in 1910 Other observers are quoted who report tuberculous bronchial glands in 87 per cent of all children dying between the ages of 6 and 16

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

AZODERMIN

(CHARLES ZIMMERMANN AND CO 9 AND 10 ST MARY AT HILL LONDON E C)

Azodermin is suggested in the place of amido azo toluol as an application for promoting healthy granulation Its constitution is that of amido azo toluol (scarlet red), in which the amido group is acetylated This has the effect, it is stated of rendering the compound non toxic, symptoms having been noticed when ordinary amido azo toluol was used which resembled aniline poisoning Azodermin appears to give particularly good results in the treatment of wounds caused by burns and even in extensive lesions a sufficiently firm covering of skin was formed without taking further measures In these cases no toxic symptoms were observed Azodermin is applied in the form of an ointment containing 8 per cent of the acetylated derivative

MAGNESIA COMPOUND

(SAVORY AND MOORE LIMITED 143 NEW BOND STREET, LONDON, W)

This is a simple and effective emulsion of the true hydroxide of magnesium We carefully examined the preparation for objectionable constituents, having regard to its application in the ailments of infancy We were not able to find any trace of alkaloid, neither was there evidence of the presence of metallic impurities In short, it consists of pure magnesia hydroxide suspended in a fluid pleasantly flavoured with simple aromatics and carminatives Whilst acting as an antacid it obviously does not develop gas, as is the case with carbonates The preparation is free from sugar and alcohol It is principally useful in fermentative indigestion, while it serves also as a mild laxative

"ILYOS STANDARD FOOD

(H W MURFITT AND SONS, DOWNHAM ROAD MILL, ELY, CAMBS)

The analysis of this cereal preparation shows that it contains a comparatively rich proportion of the individual constituents of the whole wheat berry The proteins and fats are particularly high with a corresponding reduction in the amount of carbohydrates It possesses a decidedly increased nutritive value compared with ordinary wheat flour. The following analysis supports this statement Moisture, 11 83 per cent , mineral matter, 1 70 per cent , protein, 14 70 per cent , sugar, 0 65 per cent , fat, 6 60 per cent , and starch and dextrin, 64 52 per cent The amount of substance soluble in water was just short of 30 per cent , and amongst the soluble constituents found was a decided amount of dextrin, so presumably in the course of manufacture part of the starch is converted The amount of mineral matter is further satisfactory, containing an important proportion of phosphates

SUPREME OLIVE OIL

(COSENZA AND CO , 28A CLARGES STREET, LONDON, W)

This oil is put forward as of specially pure quality which adapts it particularly, though not exclusively, for medicinal use Evidence in favour of its purity was obtained by a series of tests, directed, for example, to density, iodine absorption equivalent, and certain physical constants With each and all the oil gave perfectly normal results, evidencing that it is pure and free from admixtures with foreign oils Certain qualitative tests were also made which admitted of the same conclusions in regard to purity Finally, the acidity of the oil was measured, and it was found to amount only to 1 41 per cent in terms of oleic acid In view of these results it was not surprising to find that the oil is entirely free from unpleasant odour and taste It is a pure bland expression of the olive fruit

LA PRESTE NATURAL MINERAL WATER

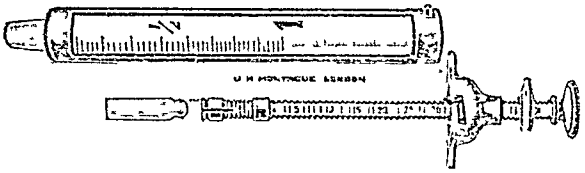
(THE PYRENEAN WATERS COMPANY, LIMITED 16, PICCADILLY ARCADE, LONDON, W)

La Preste is a health resort with a thermal establishment situated in the Eastern Pyrenees, about 50 miles from Perpignan The waters have been employed for a good many years in the treatment of affections of the urinary tract, cystitis vesical catarrh, prostatitis, and so forth The chemical analysis of the water does not offer a satisfactory explanation of its value in these disorders, for according to our examination the total solid matters do not amount to more than 11 20 grains per gallon, an amount which characterises those drinking waters known as soft Amongst the mineral constituents the following were found Silica, 3 22 , calcium carbonate, 0 14 , sodium chloride, 1 148 , sodium carbonate, 0 312 , sodium sulphate, 4 14 grains per gallon It is curious to note that silica is one of the leading constituents, although the amount of this is small However, experience has shown that a course of this water is beneficial in genito urinary diseases, and it would seem that the explanation can hardly rest on the chemical story revealed Possibly the extraordinary purity of the water—that is, its freedom from minerals—endows it with physical properties which in the *régime* of a course lead to a physiological process of demineralisation The water is warm, but no claim is made in regard to radio active properties The establishment is situated amongst charming scenery, and the accommodation provided is well appointed The water is supplied in bottles at the above agency

New Inventions.

A NEW HYPODERMIC SYRINGE.

THIS syringe has been designed with a view to embodying the good points of syringes already in common use, while doing away with such defects as are met with in many forms. The barrel of the syringe is of glass, and is in one piece with the nozzle. This latter is made specially stout in order to prevent its being easily broken off, and fits such standard needles as are supplied to the Government of India.



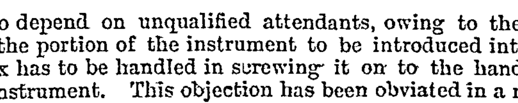
The plunger is also of glass, and this combination of glass barrel and glass plunger secures that perfect suction action such as is seen in the better types of the all-glass syringe, which is so essential if accurate results are to be yielded. To the glass plunger is affixed, by means of a special "ball and socket" joint, a metal piston-rod with a screw thread, thus allowing the dose to be accurately regulated, and so an exact fraction of the contents of the syringe to be injected, in a manner usually possible in metal syringes but not possible in the all-glass ones. The syringe is contained in a metal guard fitted with a cap that is fixed in place on the top of the guard by means of a bayonet catch, thus preventing the piston from slipping out of the barrel. There are no washers connected with any part of the syringe, and hence the disabilities often met with in syringes fitted with washers are avoided. Since the syringe is so arranged that expansion of its various parts by heat causes these to slightly separate one from another it can, with all its parts screwed up tightly and with its needle fitted on to its nozzle, be put straight into actively boiling water and sterilised by boiling without fear of breaking; while after taking it out of the steriliser the syringe is ready for immediate use without further manipulations being necessary. The plunger being of glass is not softened by boiling and so has not to be occasionally renewed. The illustrations show the syringe when taken apart and the manner in which the glass plunger and metal piston rod are connected together. I have much pleasure in thanking Dr. Charles Slater, bacteriologist to St. George's Hospital, for his valuable suggestions in carrying out this idea.

The syringe can be obtained of J. H. Montague, 69, New Bond-street, W., and is supplied as an ordinary 1 c.c. syringe with divisions of 1/20th c.c., or as a special 1 c.c. syringe with divisions of 1/40th c.c., this latter form being thought to be useful for the hypodermic administration of tuberculins; also as a 5 c.c. or 10 c.c. syringe. The special 1 c.c. syringe is here shown.

E. L. HUNT, M.B., B.S. Lond., D.P.H. Camb.,
Clinical Pathologist to Mount Vernon Hospital for Consumption, and Assistant in the Bacteriological Laboratory, St. George's Hospital, S.W.
Upper Montagu-street, W.

AN IMPROVED CERVIX DILATOR.

THE usefulness of the principle of Fritsch's cervix dilator in minor gynæcological operations is beyond dispute, but in these days when aseptic surgery is aimed at by every surgeon its usefulness is very much curtailed, especially when one



has to depend on unqualified attendants, owing to the fact that the portion of the instrument to be introduced into the cervix has to be handled in screwing it on to the handle of the instrument. This objection has been obviated in a modification suggested by me and made by Messrs. C. J. Hewlett and Son, Limited, of Charlotte-street, London, E.C. In this modification the part to be introduced is fixed on to the bar, and the lower portion of the stem of the bar can be slipped into the universal handle of the instrument, and by a slight twist of the handle a bayonet catch renders the instrument fixed for use. After dilatation, through that piece, the handle of Size 1 is unfixed and the bar of No. 2 slipped into its place. This is fixed in the same way and used. The remaining sizes are used according to graduations. Instead of 5 I have increased the sizes to 7, and have put the whole in an aseptic metal case, with folding legs. This enables the case to be used in sterilising the instrument, with the aid of a small spirit lamp, and a small clip is also included in the case for facilitating the taking out the size required without any difficulty and inconvenience.

OGUNTOLA SAPARA, L.R.C.P., L.R.C.S. Edin.,
Lagos, Southern Nigeria. L.F.P.S. Glasg.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Feb. 13th, Sir RICKMAN J. GODLEE, the President, being in the chair.

In accordance with the report of the Court of Examiners Diplomas of Membership were issued to 98 successful candidates.

It was resolved to issue, in conjunction with the Royal College of Physicians of London, Diplomas in Public Health to 12 successful candidates.

It was resolved to contribute 50 guineas to the Lister Memorial Fund.

It was resolved, on the recommendation of the Examination Committee, to make various changes in the regulations for the Primary Examinations for the Fellowship, and of these changes the most important was that in the examination in physiology two papers, each containing four questions, of which the candidate must answer only two, shall be set, and that two hours shall be allotted to each paper; and that the same arrangement shall be adopted for the written part of the examination in anatomy.

Mr. C. H. Golding-Bird was re-elected the representative of the Council on the Central Midwives Board.

The PRESIDENT reported that he had chosen Mr. G. H. Makins as Bradshaw Lecturer for the ensuing collegiate year.

A letter was read from Lady Butlin offering to present to the College a replica of the portrait of the late Sir Henry Butlin by the Hon. John Collier, which was exhibited in the Royal Academy a few years ago. The offer was accepted with appreciative thanks.

The SECRETARY reported that he had received from the executors of the widow of Mr. Cæsar Henry Hawkins a portrait by Zoffany of Mr. Pennell Hawkins, Master of the Company of Surgeons in 1778, and great uncle of Mr. Cæsar Henry Hawkins, the picture having been bequeathed by Mr. Cæsar Hawkins to his wife for life, and after her death to the Royal College of Surgeons, with the direction that it should be placed near the picture painted by Hogarth of Sir Cæsar Hawkins, Bart., brother of Mr Pennell Hawkins.

The PRESIDENT reported that Mr. W. A. Maggs's period of office on the Board of Examiners in Dental Surgery would expire on March 12th, and that the vacancy thus occasioned would be filled up at the quarterly meeting of the Council in April.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., to-day (Friday, Feb. 21st), at 8.30 P.M., when Dr. F. M. Sandwith will open a discussion on Pellagra, and read a paper entitled "Can Pellagra be One of the Diseases Due to Deficiency of Nutrition?" A paper will also be read upon "Fatal Pellagra in Two English Boys, with the Results of Pathological Investigation of One Case," communicated by Dr. Charles R. Box and Dr. F. W. Mott, F.R.S. March 21st being Good Friday, no meeting of the society will be held on that day, but it is proposed to hold the next meeting on April 18th.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 22, 1913.

The Value of Post-mortem Examinations.

THE unusual application recently made to the Divisional Court in connexion with the death of Mr. HUGH CECIL TREVANION at Hove emphasises the fact that in the interests of justice the cause of every death inquired into by a coroner should be established in the fullest possible manner. Now the evidence on such an occasion is rarely, if ever, complete until a post-mortem examination has been held, and has been followed by such analysis as may be deemed advisable, and at any time such examination may have to be supplemented by elaborate research. At the first inquest in this case, quashed in accordance with *the terms of Section 6 of the Coroners Act of 1887, it* was proved that the deceased was a young man in the habit of taking veronal to induce sleep, and that at the time of his death he had veronal in his possession. A friend living with the deceased deposed to the effect that on the *evening of his death he stated that he had taken an overdose* and he asked that a medical man might be sent for. The medical man arrived and took such steps as were suggested by the symptoms, which were entirely consistent with veronal poisoning, but the patient died. A previous occasion on which an overdose of veronal had been taken by the deceased was described by his mother. The evidence, in short, seemed to corroborate the statement referred to as having been made by the deceased, and, as there was no suggestion of any threat of suicide having been uttered, it is not surprising that a verdict of death by misadventure from an overdose of veronal was returned by the jury without such confirmation as post-mortem examination and analysis might have supplied. As a matter of fact, the question of ordering a necropsy was discussed, and the mother of the deceased was desirous that there should be an adjournment for the purpose; but apparently one of her other sons thought otherwise.

The insistence of the mother, however, led to the exhumation of the body of her son, and the submission of it to examination by Dr. W. H. WILLCOX and Dr. B. H. SPILSBURY. The result of *their examination fully justified* the action of the Home Office in the matter, for reports made by them were stated in the Divisional Court to show that veronal must have been taken by the deceased within an hour of the time when he became unconscious to the extent of *150 grains*, his ordinary habit being to take a dose of 7 grains to induce sleep, followed by a second if the first was ineffectual. The lengthy course of the second inquest was followed with close attention by all interested in medico-legal matters, but the evidence on both sides was of a kind to make it almost a foregone conclusion that the jury would in their verdict attach no blame to anyone, but would find that the sale of veronal required further restriction. The evidence has been *so fully reported* in the newspapers that it is unnecessary to recapitulate it, and it is enough to say, in dealing with the legal *aspect of the facts* proved, that the verdict of the jury was a perfectly right and proper one. It was conclusively shown that the deceased died from taking a very large quantity of veronal, probably not less than 150 grains. This was a matter of scientific evidence as the result of examination and analysis, and the amount taken by a young man who had had personal experience of the drug and of the effects of an overdose precluded the idea of "accident" in the ordinary sense. Those associated with the deceased in his flat were very few in number, and they did not pretend to know how or when young TREVANION swallowed the poison which caused his death. That he should have done so with the intention of ending his life, or of alarming his friends, was not inconsistent with his character and previous actions, but there was no evidence that he intended to do either upon the night in question. A verdict of suicide or of accidental death would have entailed the jury forming an opinion as to the question of his intention, after being satisfied *that he took the veronal knowing that he was doing so.* The alternative to a verdict upon the lines suggested above would have been one of wilful murder against some other person. Mr. ROE, a friend who lived with him, obviously had opportunities to administer poison to the deceased, in addition to which he would have been a gainer by his death, and there was some evidence, contradicted however, that he was aware of this fact. There was no evidence to indicate that ROE had anything whatever to do with the veronal being taken by TREVANION, and the difficulty of causing another person to absorb so large a quantity of the drug without observing its presence was entirely in his favour. In addition to the absence of evidence of any sinister act or intention on the part of ROE, there was evidence of an independent *character to the effect* that his undoubted influence over TREVANION was used upon many occasions to restrain him from excess, alcoholic and otherwise, when indulgence in it would probably have had the result of shortening life. Any *other verdict than that arrived at would have been* founded upon conjecture, and as no fresh evidence as to the precise manner in which young TREVANION came to die is likely to be forthcoming, that point will have to remain undetermined.

The affair has had two results of some public importance. The council of the Pharmaceutical Society has recommended the scheduling of diethyl-barbituric acid as a poison,[1] and there can be little doubt that the Privy Council will approve the recommendation. Secondly, it has been demonstrated, so far as it needed demonstration, that the cause of death in every case inquired into by the coroner should be established with the greatest degree of *certainty attainable*, and that the inquiry is incomplete if anything is left to conjecture or opinion which can be proved with certainty by post-mortem examination. In the case of young TREVANION the evidence at the first inquest seemed to point quite naturally to an accidental overdose, and this view would have received confirmation if post-mortem examination had revealed the kind of overdose to be expected in a case of accident. The case will no doubt be long remembered by coroners, and it is to be hoped that it will be understood and appreciated by public authorities, members of which are apt not infrequently to regard the cost of post-mortem examinations as an expense that coroners ought to endeavour to avoid. Mr. VERE BENSON, the coroner, summed up the case in a masterly manner, his fairness being conspicuous.

◆

When to Operate in Appendicitis.

MUCH difference of opinion still exists as to the most suitable time for the surgeon to intervene in an attack of appendicitis, and the question was made the subject of a debate at the Medical Society of London on Feb. 10th. The discussion, which we publish elsewhere, was opened by a paper, which has already appeared in our columns,[1] from Mr. EDMUND OWEN, who spoke strongly in favour of operation in all cases of appendicitis as soon as possible after the disease has been recognised, and he was followed by a number of other surgeons who held the same views. The debate may therefore leave the impression that no other views are possible, and it is unfortunate that Sir GEORGE BEATSON, who had arranged to present the arguments of those who advocate a waiting policy, was unable to be present. No one supported this attitude, and there were no real differences of opinion expressed, for the only divergences that were mentioned referred merely to the management of certain of the details of the operation. It can hardly, therefore, be claimed that the discussion has enlarged our knowledge. No new suggestion was brought forward in favour of a waiting policy; but the reasons for adopting immediate operative treatment were well put, and their presentation by a number of surgeons showed, more clearly than if only one surgeon had spoken, the basis on which is founded the immediate operation for appendicitis.

The diagnosis of inflammation of the appendix does not, as a rule, present any difficulties. The localisation of the pain, the fixation of the abdominal muscles, often the presence of a palpable swelling in the neighbourhood of the right iliac fossa, with the added symptoms of inflammation, are, taken together, sufficient to indicate the condition. It is true that occasionally some of these signs and symptoms may be absent, and yet inflammation of the appendix may be present, but these cases are exceptional, and even in them it is nearly always possible to recognise the appendicitis when it exists. The difficulty arises after the diagnosis has been made. Should an operation be performed, and if so, when? There are those who claim that a very large proportion of the cases of appendicitis would recover even if no operation were performed, and urge that if an operation be done in every case as soon as the diagnosis is made, a great many unnecessary risks will be run by the patients. There is an element of truth in this statement. It is certain that there are cases which recover even if no operation be done, but it is by no means easy to determine in what proportion of instances this is true. While some put the percentage as high as 50, and some, indeed, even higher, it is probable that 30 per cent. would be a more accurate estimate. Some surgeons say that in mild cases it is better to postpone the operation to the "quiet interval" when all the inflammatory symptoms will have ceased, and when the operation of appendicectomy can be performed with a greater measure of success. It is true that the delayed operation is associated with a very small mortality; in fact, with many operators it may be said that no deaths occur after operations performed during the quiet interval. This is doubtless a very strong argument in favour of waiting until the acute symptoms have subsided, but the difficulty exists that it is not really possible to distinguish which cases may be safely left in this manner and which must be submitted to operation immediately the diagnosis has been made. There are cases whose only chance of life depends on an immediate operation, when the inflammation of the appendix is so severe that it has given rise to sloughing and acute perforation of the appendix. Should these cases be left, no quiet interval will ever arrive, but there will occur within a very short time an attack of septic peritonitis. The attack will be so intense that no time will be allowed for the localising of the sepsis by the formation of peritoneal adhesions; the peritonitis will be diffuse and a fatal result is practically certain. It may be answered that it is possible to distinguish these fulminating cases from the more common forms of appendicitis, and that an operation might be performed without delay in those cases in which the attack seemed to be of the intensely acute character. When, however, an attempt is made to draw up the diagnosis between various forms of appendicitis great difficulty is experienced in finding pathognomonic symptoms or signs. The temperature is of some value, but it is not absolutely trustworthy, for in some of the cases of the greatest severity the temperature may be not at all raised, even though a general peritonitis has commenced. The pulse is of more significance than the temperature, but it cannot be absolutely trusted, for in very severe cases there may be no increased frequency of the pulse. The sense of muscular resistance over the inflamed appendix is certainly of value in the diagnosis, but all surgeons with much experience have seen cases in which no resistance can be felt even though the inflammation is acute. The general aspect of the patient is worth something, and the sensation of pain is also important, but the surgeon who relies on these will sooner or later find that his trust has been in vain. There is no infallible way of deciding that the inflammation of the appendix is certainly of a mild form, and may with perfect safety be left until the quiet interval has arrived, and this, of course, is the great argument for immediate surgical interference.

At the meeting of the Medical Society of London the speakers were in practical unanimity in saying that in all cases the operation should be performed as soon as the diagnosis has been made. Some held that if an abscess be found the surgeon should content himself with the opening of the abscess, and should postpone the removal o a later date, unless the appendix should present itself in he wound With this exception, all agreed that the sooner he appendix was out of the body the better. Not until the appendix is removed can the surgeon feel certain that it may not form the starting point of an acute peritonitis Many a time has it occurred that the surgeon has been able to emove an appendix on the very point of bursting, sometimes it has given way as it was being lifted with all gentleness out of the abdomen Only too often it has happened in the past that the surgeon has found that even a delay of a few hours has sufficed to give rise to an acute peritonitis In these circumstances surgeons feel and express themselves strongly with regard to the policy of procrastination, claiming that nothing but immediate removal of an inflamed appendix will offer the best chance of a successful issue

The Biological Basis of Specific Therapy.

THE details which go to make the treatment of specific diseases by anti bacterial remedies a practical success are many, and our knowledge of them is still in course of formation The treatment of such disorders is, in principle, a branch of parasitology, and therefore, like the treatment of grosser parasitic infections, largely a matter of attention to detail General principles do not take us far in the treatment of parasitic disorders, because success is mainly a question of getting a recognised specific remedy into effective contact with the parasite, and such a result is not to be compassed easily in microbic infections It is one of the drawbacks to Professor EHRLICH's *well known theory of immunity* that it makes the process of resistance to an infecting organism more simple than it probably ever is in reality The infecting organism is represented generally either as being phagocytosed, or else agglutinated or bacteriolysed by one or other of the hypothetical series of bodies whose pre existence in all of us is invoked as the explanation of sundry observed phenomena, where probably several of these actions cooperate together to produce the result To get a similar effect artificially will not be easy, and this explains, no doubt, many instances of failure in specific treatment with sera and vaccines

An even greater obstacle to the effective treatment of parasitic disorders of every kind is the difficulty of bringing the remedy into effective contact with the parasite Parasites being highly specialised beings in their manner of life, their habit is to settle themselves in situations where they will be as far as possible beyond the reach of anything noxious to them, and the result is that they are always difficult to dislodge. If this were not so, parasitic disorders would not exist The medical practitioner, therefore, who sets himself to eradicate an infectious organism from any host, is facing no easy task; and though we may talk of bringing protective bodies into contact with bacteria, as a matter of fact such organisms locate themselves where, each in its own way, it will be beyond the reach of such a means of defence Dr SIMON FLEXNER has given a very good example of this in the case of the organisms which cause various descriptions of meningitis The cerebro spinal fluid is a non albuminous liquid, and therefore the immune bodies in the blood penetrate into it with great slowness, whilst, on the other hand, the antibodies formed have no difficulty in getting out of it into the blood It is consequently quite easy to manufacture protective sera against these forms of meningitis, but to get them into effective contact with the bacteria the method of lumbar puncture is indispensable Similar reasons make Bier's bandage so beneficial in the treatment of infections of the joints, which, for anatomical reasons, are not very vascular structures Though these are instances of the simplest kind, we may be sure that every other micro organism, like every grosser parasite, contrives so to locate itself in the body of its host as to be to a very considerable degree protected against unfavourable influences of every description The user of anti bacterial sera and vaccines should, therefore, not be too optimistic about his chances of getting them to go where he wants them to go

In the course of a bacterial infection the type of the organism may mutate or change into something else which may be either less virulent or more virulent than the original strain In the former case a featureless recovery occurs, but in the latter case the patient will succumb unless he can manufacture a new set of immune bodies to cope with the new adversary The phenomena of relapses or exacerbations in the course of a disease receive a good deal of support from such a hypothesis, amelioration being effected through the original strain of the organism being dominated by the protective mechanism to a certain extent, and then a new variety starting up which requires the business of cure to be begun again *The physician will be on the alert to this possibility*, and it is most true that infectious disorders of all kinds are most liable to be scotched and not killed. Dr FLEXNER suggests that, wherever possible, such variants or mutants, in Mendelian phraseology, should be isolated and employed for the purpose of making extra sera or vaccines, to be used upon the same or other cases We have, of course, in this the germ of the idea of using polyvalent serums, only the organisms used in making such serums should not be selected at random It will be manifest to the practitioner of medicine that if he is going to enter upon therapeutics of this refined order, the bald, sketchy views of serum therapy with which most people are satisfied will not be sufficient for him There is a tendency undoubtedly to regard serum-therapy and the analogous use of bacterial vaccines as something that will make the practice of medicine more easy in the sense of saving trouble This is a serious mistake The new modes of treatment may make the art of medicine more efficient, but they do not call for less use of the intelligence, and, as we have already observed, the eradication of parasitic organisms is never in any case a matter of easy accomplishment, because they are all of them in their different ways well protected against disturbance, though the fact may not be apparent at first sight Were it otherwise there would be no such thing as a parasitic disorder We must all of us go about the business of specific therapy heedfully, undazzled by the promise of quick success which a novel remedy always seems at first sight to hold forth

Annotations.

"Ne quid nimis."

THE ADMINISTRATION OF THE PHARMACY ACTS.

THE annual report of the Registrar of the Pharmaceutical Society, which was presented to the council at the February meeting, contains *inter alia* an account of the work done last year in connexion with the administration of the penal clauses of the Pharmacy Acts, from which it is evident that the duty of preventing as far as possible the irregular sale of poisons is no light one. The number of cases of alleged infringement of the Acts which are reported and require investigation each year tends to increase rather than to diminish, but this is not necessarily because of greater laxity on the part of sellers of drugs, but partly because of the considerable growth in recent years in the number of persons who are entitled to traffic in poisonous substances. The number of names on the Pharmaceutical Register is fairly constant from year to year; the increase during the last decade has been considerably less than a thousand, the present Register consisting of the names of 16,330 persons. In 1909, however, a new class of poison sellers was created for the purpose of retailing, under a licence, poisonous preparations for use in agriculture and horticulture. The intention was that licences to sell such substances should only be granted to unqualified persons trading in districts where the existing facilities for obtaining them from chemists' shops were insufficient, but the local authorities which grant the licences have in many instances disregarded this intention, with the result that the sources from which potent preparations of arsenic and nicotine can be obtained readily are unnecessarily numerous. The work of supervising the distribution of poisonous compounds is therefore more onerous than it was prior to 1909. But the growth in the number of suspected cases of the irregular selling of poisons which the legal department of the Pharmaceutical Society has to investigate is not solely due to the increase in the number of poison-sellers, but is partly the result of other obligations imposed on the society by the Poisons and Pharmacy Act of 1908 and of the process of "speeding up" which is going on all round. This Act requires the certificate of qualification of the chemist by whom a pharmacy is conducted to be exhibited in every shop, and it is the duty of the legal department to ascertain if this requirement is being fulfilled. The report of the society contains no statement concerning the manner in which this regulation is being observed, but it is probable that among the reported cases of alleged infringement of the Acts were some in which the certificates were not exhibited. Last year a large number of shops were visited with the object of finding out if the certificates were exhibited, and since the Act came into operation practically all the pharmacies in the country appear to have been inspected. In the interests of the public this is a wise step to take, but, curiously enough, no public money is spent upon the work which the administration of the law relating to the sale of poisons and the business of the chemist entails. The report states that the number of pharmacists who are registered as superintendents of companies carrying on the business of chemists is 459, but as some of these companies have many branch shops it is not possible from the figures to calculate how many chemists' shops are under the control of joint-stock companies; it is common knowledge, however, that the number is increasing. During 1912, the year with which the registrar's report deals, 1362 cases of alleged infringement of the Act were investigated; this is an increase of rather more than 100 on the immediately preceding year, but compared with the year 1906 the increase is nearer 1000. It was only necessary, however, to institute proceedings in 238 cases last year, from which it may be inferred that the majority of cases reported were found on examination to have involved no irregular practice of more than a trivial nature. The class of offence which seems to be most common among unqualified persons is the dual one of keeping open shop for the sale of poisons and selling poisons; both practices are contrary to Section 15 of the Pharmacy Act, 1868, and the penalty for each offence is £5, recoverable through a county court. The use by unqualified persons of the statutory pharmaceutical titles is occasionally one of the offences committed, while the report shows that in several instances the council commenced proceedings against chemists who used the letters "M.P.O.," implying that they were members of the Pharmaceutical Society when such was not the case. Proceedings were also instituted against persons who had failed to observe proper precautions in selling scheduled poisons, but in the majority of cases the offenders were unqualified proprietors of drug stores. In eight cases of alleged infringement of the Acts it was found upon analysis that the poison asked for had been omitted from the preparations sold, and proceedings could not therefore be taken under the Pharmacy Acts. In three of these cases the vendors had sold compounds labelled "Paregoric" which contained no opium and were, therefore, not prepared according to the British Pharmacopœia; the vendors were proceeded against under the Merchandise Marks Act for applying a false trade description to goods and for selling goods to which a false trade description was applied and a conviction was obtained in each case. The report shows that the membership of the Pharmaceutical Society is steadily increasing; the society is now larger than at any period in its history.

THE ORIGINAL HUNTERIAN MUSEUMS.

THE examination of old museums is a fascinating if neglected branch of antiquarianism. The manner of acquisition of museum specimens is apt to be entirely overlooked by the makers of scientific catalogues, yet how delightfully such books would read if they were adorned with some such anecdotes as that which concerns the now extinct dodo. The dodo's feathered skin was brought to England by an old traveller and handed over to Sir John Tradescant, whose collection was afterwards known as the Ashmolean. In time it grew mouldy and was condemned to destruction in 1755 by some curators of a too exclusively classical education. Seeing the interesting relic on the already smouldering pyre, a passer-by cut off the dodo's head and one of its feet, and these, with another foot, a painting, a book illustration, and a few bones, are all we have now of the dodo. Again, there is the romance of how John Hunter acquired the skeleton of the Irish giant, placed in the Museum of the Royal College of Surgeons of England. The story is too well known to warrant re-telling, though the hearers of Sir Rickman Godlee's fascinating Hunterian Oration (see p. 507) were reminded of it when he pointed out on a well-drawn projection of Clift's plan of Hunter's Leicester-square house as it appeared in 1792 the discreetly private side door, "where Mr. Huger met the Irishman." Huger was doubtless Hunter's man, and "the Irishman" was the corpse of Mr. Byrne, the giant, dead of drink and consumption at the early age of 24. In his haunting fancy "The Child in the House" Walter Pater has described the potency of early domestic memories in the formation of an individual's psychic content. Clift was only a poor lad when in 1792 he came to work under John Hunter's directions in the original Hunterian Museum, and at a distance of 40 years we find the pathetically faithful servant, now become conservator, able to sketch from memory at dead of night—his tiny pretty plan being dated 2 A.M., Nov. 1st, 1832—every little detail in the once-adored museum house. Thus he has set down such delightful trifling matters as the situation of Mrs. Hunter's sedan-chair, of Mr. Hunter's "afternoon bedroom or sofa bed," "great red japanned army chest" between the windows of the "House pupils' room," pictures such as "Harlot's and Rake's Progress," drawbridge, yard for washing whale and carriage, and books, prints, and "dry preps. pathological." The plan gives a good idea of an eighteenth century museum, and we are struck by certain very modern touches. Thus, Hunter's desk was of the slide-top kind, and the theatre and other rooms were warmed—very badly, says Clift—by hot air from two of Jackson and Moser's stoves. Of the backyard it is recorded that "no grass grew," and that it was called "the garden"; there were also deep areas, as there might be now. Clift has left one of his careful MSS., containing minute details as to the expense of shifting the Hunterian Museum in wagons from Leicester-square to Lincoln's Inn Fields. Another of his small sketches represents the Museum in 1810. This was admirably reproduced on a large scale to illustrate the Hunterian Oration this year, and though it shows dignified vistas of vaulted roofing it is hard to discover where the specimens were shown. We know, however, that Clift devoted his laborious life to the setting out of the fine Hunterian specimens, contained in red-stoppered bottles, of which there remains Clift's MS. list. The same indefatigable worker alludes, in his curious unpublished year books of work done, to a forgotten function of the College, the fitting out of the scientific side of several famous Arctic expeditions. Of these expeditions only printed records remain in the College library, but at the present time it would be of great public interest if any relics of Ross, Franklin, and others could be unearthed and exhibited. Captain Cook's little MS. log-books, for instance, now form part of the priceless Marsden Library at King's College, London. In these appears the list of the names of the crew of Cook's ship according to the Otahitian pronunciation. The Captain himself figures as "Tute," and by this name recent travellers tell us he is still known by the descendants of the men who murdered him because they loved him so well that they wished to retain his divine ghost in their midst. Museums and libraries, in fact, are romantic through the associations of their contents, among which lurk unconsidered details often strangely confirmatory of fact observed at the ends of the earth.

UNUSUAL ILLNESS AMONG WEAVERS OF COTTON CLOTH.[1]

CASES of primary aspergillosis are very rare, and in an account of illness affecting weavers in four sheds in Lancashire Dr. E. L. Collis suggests that this was the most likely cause. The symptoms developed very acutely with febrile disturbance, asthmatic attacks, and characteristic cough. The process common to all the weaving sheds in question differed from the usual manufacture of cotton cloth in that addition of the antiseptic zinc chloride (usually added to prevent occurrence of mildew on the cloth at a later stage) was omitted, as dyers specify that no chlorides shall be present in the cloth. Obviously cotton threads passed through size and quickly wound, while still containing moisture, on to the warp beam, furnish conditions favourable to the development of moulds. Under such circumstances mildew is not infrequently seen, but in these cases more attention seems to have been given to the unpleasant odour given off from some of the warps, suggesting the possibility of the liberation of gas, than to the isolation of the fungi present. (Di-ethyl-arsine liberated when penicillium brevicaule grows on arsenical wall-papers is an example quite to the point.) Neither the symptoms among the weavers nor chemical analysis, however, lent support to the view that injurious gases were a cause of the trouble. No unusual mould was found in the sputum, so that it is only by inference that the theory of aspergillosis was arrived at. The remedy for the condition which has proved effective—addition of formaldehyde to the size—also favours it. Primary pneumomycosis is noted by Rolleston and Latham, in accordance with the description of Chantemesse and Widal, as an occupational disease among two very small classes of persons in Paris: (1) those making a bolus of seeds in the mouth as a preliminary to artificially feeding pigeons; and (2) hair sorters who inhale the flour of rye used to enable them to separate the hairs more readily. Both aspergillus fumigatus and aspergillus niger are parasitic and believed to produce morbid changes in the human body. In this connexion a remarkable account is given in the December issue of the *Journal of Hygiene* by G. Massee, of the Jodrell Laboratory, Kew Gardens, of a fungus, cladosporium herbarum, which produces black spots on the surface of chilled meat. In its adaptation to this unusual substratum the fungus has so far departed from the normal type of species that the typical form of reproduction by spores has been abandoned and has been replaced by a secondary and lower form of reproductive bodies—chlamydospores—immersed in the substratum produced from specialised cells of the vegetative hyphæ of the fungus.

DWARFISM ASSOCIATED WITH DYSTROPHY OF BONES AND MUSCLES.

ABOUT a year ago M. Hutinel, of Paris, gave a description of a peculiar form of retardation and perversion of growth which he had been able to separate from the crowd of indefinite cases of malnutrition attending his hospital clinic. Since that time—indeed, within a few months—Dr. Leon Tixier and Dr. Carle Rœderer have observed four examples of this form of dwarfism, which are briefly recorded, with a summary of the chief features of the condition, in *La Presse Médicale* of Feb. 1st. Three of their four patients were members of one family—indeed, of the same generation of that family; their mother showed traces of bony abnormalities similar to those exhibited in grosser form by her children. The most obvious of these abnormalities is inadequate stature, the patients falling short of the average height by 10 or 20 per cent. This is partly due to curvature of the long bones and of the spine, partly to retardation of the ossificatory process by the abnormal state of the diaphyseal cartilage. The first symptom noticed, however, is difficulty in learning to walk; this is accompanied by an antero-external curvature of the tibiæ. In the arms a similar deformity is present, though it is less pronounced. The femora and humeri are also curved outwards, and there is marked genu valgum. Scoliosis is a constant and striking feature; with it there is a lordotic curve in the lumbar region, and the usual secondary changes in the thorax and pelvic and pectoral girdles. In these as well as in other respects the bony changes closely resemble those of rickets; as in the commoner disorder, there are epiphyseal thickenings, and the frontal bones are prominent. Radiographic examination, however, reveals several features which seem to hint at a different type of morbid process being responsible. There are evidences of attempts at repair, the concavities of some of the curves being reinforced by thickening of the bone. The medullary canal of the long bones is large, as in rickets; but its outline (as seen in the radiograph) is irregular, as in syphilitic osteitis. In the cases recorded by Dr. Tixier and Dr. Rœderer the Wassermann reaction was negative, and there was no reason to suspect a syphilitic basis. In one important respect the skiagraphic appearances recall those of osteomalacia; the shafts of the long bones cast a stippled shadow, apparently due to a disorderly commixture of non-calcified with normal areas. The muscles are generally weak and exhibit a diffuse dystrophy; this is too definite to be regarded as a result of the child's immobility, and must be looked upon as a primary feature of the disorder. The intellect is often feeble, and the evolution of the mental powers retarded; in one case there was obesity, in others the children were wasted. In one instance sexual development was delayed. Apart from the possibility of the hereditary factor alluded to above, nothing is clear as to the causation of this singular affection; neither has there been any appreciable benefit from any particular line of treatment. It is possible, of course, that other critics may find the separation of this condition from rickets an arbitrary and unjustifiable one; yet in its later development and in some other features its claim to individuality does appear reasonably well founded.

---

[1] Report on Unusual Illness among Weavers of Cotton Cloth. By E. L. Collis, M.B. Oxon., H.M. Medical Inspector of Factories. London: Darling and Sons, Limited. 1913.

A FLANNELETTE BILL.

A BILL has been introduced into the House of Commons and read for the first time, entitled "A Bill to deal with Misdescription of Fabrics," the object of which is to prohibit the sale of flannelette or any other textile fabric described as being non-inflammable or safe unless it conforms to such standard of non-inflammability as may be prescribed by regulations to be made by the Secretary of State. It may be remembered that in 1910 a report was issued by a Home Office Departmental Committee upon the inquiry into the question of the danger arising from the sale of flannelette for articles of clothing, and legislation was recommended making it penal to describe as uninflammable material which will not stand certain prescribed tests. The Bill is based upon this finding, although the Departmental Committee expressed the opinion that the question of misrepresentation could be dealt with under the provisions of the Merchandise Marks Act, 1887. It has since been decided, however, that a separate Bill was necessary, as there were difficulties in the way of including a special matter such as that of the inflammability of fabrics in any existing Act. The question as to whether or not a fabric is safe or non-inflammable can, of course, only be decided by test, and this means the setting up of a standard, and here there will be some trouble in regard to getting a general endorsement from all concerned as to its efficiency or fairness. We ourselves made an attempt to lay down a standard method of testing which we considered would, if adopted, afford sufficient protection. It is required to know, in our opinion, what is safe and not what is non-inflammable, and that consideration led us to employ a test which may have passed inflammable materials, but which readily discriminated the reasonably safe from the obviously dangerous. The ordinary linen or calico night garments are, of course, inflammable, but their liability to catch fire and the spread of the flame is not of the alarming nature experienced with the common forms of flannelette. But there are superior flannelettes which are as reasonably safe as linen or calico. The Departmental Committee referred to were adverse to certain suggestions which had been made in favour of precipitate and drastic legislation, for they held that "legislation of the kind suggested is the less justifiable in view of the fact that matters may in course of time be expected to right themselves." Again, they reported that "great improvement has already been made in the manufacture of flannelette, and further improvements may be anticipated"; and finally, they expressed the opinion that "there is also the possibility that new and cheaper methods of diminishing the inflammability of the material may be discovered." It is, we think, unquestionably the case that the cheap and clearly unsafe flannelette has been responsible for bringing disaster to many helpless little ones, and the fact that such flimsy material can be sharply discriminated from the reasonably safe fabric should render the adoption of a protective test conducted under practical conditions feasible, workable, and fair. With a standard imposed, we think that good will come of the Bill, for it is obvious that the manufacturer who is not honestly able to stamp his goods as "safe" will eventually have to make room for those who can.

NON-MALIGNANT CANCER OF THE BREAST.

THAT cancer is a progressive disease leading to death, except when it has been completely extirpated by operation, is so generally true that the exceptions are overlooked. Many well-authenticated cases of spontaneous recovery from cancer are now on record, and the possibility of this occurring is forgotten by those who claim recovery from some medicinal treatment. Another and even less recognised exception to the rule that cancer is a fatal disease is the condition called "non-malignant cancer," an expression which at first may seem a contradiction in terms, but the meaning of which will be plain if it is remembered that it is the structure of a growth and not its destructive effects which determines whether it is to be classed as a cancer or not. Some years ago at the Pathological Society of London Dr. S. Bontor reported, under the title of "Non-malignant Cancer of the Breast," the case of a woman who died at the age of 77 years, and had a growth in the left breast for 23 years.[1] It never ulcerated or caused pain, but latterly there had been some inconvenience from a sense of constriction of the chest. There were several secondary deposits in the right breast and in the skin of the abdomen, but there were no enlarged glands or signs of involvement of distant organs. The cancerous nature of the growth was proved by both macroscopic and microscopic appearances. In the discussion which followed Sir Watson Cheyne referred to a case in which a similar condition had lasted for 14 years and then a sudden outburst took place. Mr. C. A. Ballance mentioned the case of a woman who at the age of 70 developed carcinoma in both breasts. The disease had no effect on her general health and she did not die until the age of 82. He pointed out that carcinoma supervening in the aged is of slow growth. In the *Australian Medical Journal* of Dec. 28th, 1912, Dr. M. Crivelli and Dr. A. J. Trinca have reported a case of carcinoma of the breast of 47 years' duration. The patient was a married woman who since the beginning of the disease has been under medical observation. At one time the growth was declared inoperable and she was told she had only a short time to live. She came under Dr. Crivelli's care 20 years ago. She stated that she first noticed a lump in the right breast 27 years before. It commenced in the region of the nipple as a hard nodule which grew very slowly for about 10 years and never became very prominent. During the next 35 years it remained more or less quiescent, a process of growth and scarring taking place During this time she enjoyed fairly good health Then without apparent reason rapid growth towards the subclavicular region commenced in January, 1910, and glandular infection was observed, first in the axilla and then in the neck and mediastinum, rapidly producing complete brachial paralysis and two months later dysphagia Inability to swallow even small quantities followed and she died from inanition on June 9th 1912, at the age of 93 years and 11 months *For 35 years the condition presented was* a prominent central nodule in the breast with a smaller circle immediately surrounding it The right arm was fixed at all the joints, the forearm and wrist being in a position of marked flexion and the skin shiny and atrophic The arm was completely paralysed and anæsthetic except in the area supplied by the ulnar nerve, which was hyperæsthetic *and hyperalgesic Microscopic examination of* portions of the growth removed after death showed that the older portions consisted of large tracts of degenerated poorly staining fibrous tissue with occasionally small groups of what appeared to be carcinomatous cells in lymph spaces The more rapidly growing portions were more cellular There never was any doubt as to the cancerous nature of the tumour, for although for many years there was no glandular involvement there was from the beginning dense adhesion to skin and underlying structures The case shows well how a prognosis based on the general course of a disease may be falsified It breaks the record of all published cases of mammary cancer of long duration In addition to the cases mentioned above durations of 15, 17, 20, and 32 years have been recorded

---

WOODHALL SPA WATERS

THE waters of Woodhall Spa, in Lincolnshire, are unique in the fact of containing important quantities of bromine and iodine, chiefly in the form of bromide and iodide with, it has been stated, some amount of bromate and iodate A recent analysis of these waters has been made by Dr J C Thresh, who records some interesting observations in regard to the methods adopted in analysis which presented some difficulties, and to the variations which occur in the amount of bromine and iodine in the water taken from different adits Not only did the iodides and bromides vary, but the chlorides and sulphates also and especially the latter Some samples contained a mere trace of sulphates, others a large quantity, hence the composition of any particular sample would depend upon the proportion in which these adit waters were mixed There is one constituent of most of these adit waters which has not yet been recorded and which is the cause of all the difficulties which arise in making the analyses This is nitrous acid, no doubt existing as sodium nitrite It is a very variable constituent, sometimes present in infinitesimal quantity and at others present in abundance In the Royal Hotel water neither free iodine nor any iodate was detected and the iodine as iodide has varied from 2 0 to 2 4 mlgr per litre There is a trace of bromate, and the bromine as bromide has varied from 39 7 to 43 36 mlgr per litre In other words, there is apparently less bromine present than is stated on the label, and only about one tenth of the iodine Whatever the composition of the water may have been at some previous period it certainly, judging by Dr Thresh's examination, differs greatly at the present time from the composition as stated on the label The Spa Company's water does not pretend to contain such considerable quantities of iodine, yet actually it is richer in both iodine and bromine than the hotel spa water now being supplied in bottles The mean of two concordant analyses of the Spa Company's water gave iodine as iodide and iodate 6 0 stated on label 5 87 mlgr per litre, bromine as bromide and bromate 76 6, stated on label 33 75 mlgr per litre Samples from the various adits in this well examined a short time ago gave iodine varying from 3 3 to 6 3 mlgr per litre and bromine from 46 5 to 65 8 mlgr per litre One of the adits yielded a water containing a large quantity of sulphates, in this respect resembling the water from the Royal Hotel well, but the others contained mere traces of these salts As Dr Thresh points out, it may be of importance to the profession to know which of the wells yields the more highly charged water, and the desirability of amending the statements of the labels on the bottles is obvious The results of the analysis convey no imputation whatever—they simply prove the extreme difficulty of defining natural mineral waters by permanent formulæ

GONOCOCCAL SEPTICÆMIA

IT is only within recent years that it has been recognised that the gonococcus is capable of causing a general infection of the blood, a septicæmia, comparable to the results of the attacks of streptococci and staphylococci The affection appears to be rare, if we may judge from the recorded cases, though it is not improbable that it occurs more frequently than diagnosis would suggest and that many of the cases of septicæmia of obscure origin are really gonococcal In the present number of THE LANCET Dr Claude B Tudehope records a case of this nature (under the care of Dr J Aldington Gibb), in which there was a blood infection as shown by the symptoms, and with it was associated a gonococcal urethritis That the pyæmic or septicæmic condition was due to the gonococcus was probable from the presence of a gonococcal urethritis, but the causal connexion was shown by the effect of the treatment with a gonococcal vaccine It would, perhaps, be well that other obscure cases septicæmic in character, should be specially examined for the gonococcus in the usual sites such as the urethra and the vagina and also in the blood The extreme frequency of gonorrhœa makes it not improbable that many cases of blood infection arising from the inflamed mucous membrane are not diagnosed as gonococcal in origin

THE ANNUAL CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH

THE Twenty first Annual Congress of the Royal Institute of Public Health will be held this year in Paris, from May 14th to 18th inclusive, upon the invitation of the municipal council A French organisation committee has been *formed representative of the great departments of* State under the presidency of Professor Landouzy, Dean of the Medical Faculty, and the honorary presidency of M Steeg, Minister of the Interior The Minister of Foreign Affairs, in extending his patronage to the congress has directed the special attention of all other interested departments in particular the Ministries of War and Marine, to the "great importance of participation in the work" The meeting will be held in five sections viz —(1) State Medicine, (2) Bacteriology and Comparative Pathology, (3) Eugenics and Child Study, (4) Naval Military, and Colonial, and (5) Industrial Hygiene Facilities will also be afforded for visiting the various public health and educational institutions in Paris Invitations to appoint delegates have been sent to all the municipalities in this country, county councils, local authorities, universities, learned societies and other public bodies and these invitations have met with cordial response. The meeting last year in Berlin was most *successful and it is* anticipated that the further opportunities which will be given this year to members of the congress for becoming practically acquainted with continental institutions will ensure a like result. All communications on the subject should be made to the honorary secretary-general of the congress, Royal Institute of Public Health, Russell-square, London, W.C.

OCCLUSION OF THE INFERIOR VENA CAVA AS A RESULT OF INTERNAL TRAUMA.

At the Pathological Section of the Royal Society of Medicine on Tuesday last Mr. S. G. Shattock recounted the extraordinary case of the late Dr. W. Rivers Pollock. Dr. Pollock, the late obstetric physician to the Westminster Hospital, as was well known to his friends, lived for 25 years with occlusion of the inferior cava, and bequeathed to the Royal College of Surgeons of England for dissection the parts involved. In 1884 Pollock, when about 24 years of age, ran successfully for Cambridge against Oxford in the 120 yards hurdle race, the time being given as 16 seconds.[1] He held his breath the whole time of the race, and immediately after the struggle lay down on the grass. Œdema of the legs supervened at once. He kept his bed for six months, during which time progressive dilatation of the superficial veins occurred. During the rest of life the distended veins were supported by the systematic use of elastic pants. Death took place from tonsillitis and septicæmia 25 years later. The dissection showed a complete obliteration of the inferior cava below the hepatic veins. The most probable view of the lesion was, in Mr. Shattock's opinion, that under the abnormal distension to which the vein would be subject some rupture of the inner coats occurred; that this was followed by an intramural extravasation whilst the exertion was still in progress; and that, as a result, when the pressure was relieved the calibre of the cava would be reduced and clotting extend into the lumen so as to complete the occlusion. It was characteristic of Pollock that he should desire that science should have the benefit of any lessons that could be drawn from the physical tragedy of his life; and Mr. Shattock's account of the pathology of his case will bring back to the memory of Pollock's many friends his splendid courage under his terrible ordeal.

RAPID MIGRATION OF A FOREIGN BODY IN THE HAND.

It is well known that small metallic foreign bodies lodged in the tissues may migrate from one place to another. Well-authenticated cases have been recorded of needles which had been swallowed being removed, after longer or shorter periods, from various parts of the body, including the extremities. As a rule fragments of needles which have passed through the skin do not move far, though muscular action or pressure from without may cause some migration. The following case, recorded in the *Boston Medical and Surgical Journal* recently, by Professor A. Lothrop, of the Harvard Medical School, is exceptional in the rapidity and extent of the migration. While dusting, a young woman wounded her hand with a needle which broke. She removed a fragment and went next day (Dec. 2nd, 1911) to the Boston City Hospital. There was a puncture on the palmar aspect of the thumb at its base. A skiagram showed a fragment of needle about a third of an inch long embedded in the tissues anterior to the semilunar bone. There was no clinical evidence of this location, which was considerably internal to the point of entrance. On Dec. 8th, prior to operation, a second skiagram was taken. This showed a fragment of needle, of the same size and shape as seen about a week previously, anterior to the distal end of the first phalanx of the little finger. There were no symptoms or signs indicating this new position of the foreign body or the fact that it was no longer in front of the semilunar bone. A median longitudinal incision about half an inch in length was made over the middle phalanx and carried through the fascia to the tendon sheath, but the fragment could not be found. The sheath was opened and the fragment was easily found lying loosely on the tendon. Uninterrupted recovery ensued. The wound of entrance showed that the fragment of needle, about one-third of an inch long, entered the radial side of the palmar aspect of the base of the thumb. Forty-eight hours later it was at about the same horizontal level on the ulnar side, and a week later it was in front of the first phalanx of the little finger. Dr. Lothrop thinks that its course must have been through tendon sheaths. The case shows the importance of taking a skiagram shortly before attempting the removal of a foreign body, which should be located by plates taken in two planes. Occasionally surgeons have much trouble in finding buried needles, and frequently they have, to their chagrin, been compelled to abandon the search.

A special meeting of Fellows of the Royal Society of Medicine will be held at the society's house, 1, Wimpole-street, W., on Monday, March 10th, at 5 P.M., when a discussion on Alimentary Toxæmia: Its Sources, Consequences, and Treatment, will be opened. The following opening addresses will be delivered on that day:—Dr. Hale White, General Survey; Dr. F. W. Andrewes, the Bacteriology of the Alimentary Canal; Dr. Vaughan Harley, the Toxins of the Alimentary Canal; Dr. Robert Saundby, Consequences and Treatment from a Medical Point of View; Mr. Arbuthnot Lane, Consequences and Treatment from a Surgical Point of View; Mr. J. F. Colyer, Consequences and Treatment from a Dental Point of View. The discussion will be reopened by Mr. J. B. Lawford on Monday, April 14th, at 5 P.M., and will be continued on successive Mondays for as long as may be necessary.

On the suggestion of the High Commissioner for Cyprus the Secretary of State for the Colonies has arranged that a visit shall be paid to the island during March, by Sir Ronald Ross, late professor of tropical medicine in the University of Liverpool. The object of the visit is to investigate the causes of the prevalence of malarial fever in the island, and to advise in regard to the best means of combating the disease.

At a meeting of the Hunterian Society, held at St. Bartholomew's Hospital on Feb 12th, Mr. A. H. Tubby, the President, being in the chair, the annual oration was delivered by Dr. Edward W. Goodall on Serum Sickness.

The death has occurred of Sir Thomas Chavasse, F.R.C.S. Eng., for over 30 years surgeon to the Birmingham General Hospital.

We also have to record the death of Dr. A. B. Duffin, consulting physician to King's College Hospital, London.

Literary Intelligence.—Messrs. J. and A. Churchill are about to publish a new book entitled "The Difficulties and Emergencies of Obstetric Practice," by Dr. Comyns Berkeley and Mr. Victor Bonney, obstetric and gynæcological surgeons to the Middlesex Hospital. The illustrations are all original and very numerous. The same publishers have just ready the sixth edition of "A Short Practice of Midwifery," by Dr. Henry Jellett, master of the Rotunda Hospital, Dublin. The new edition is to be issued with a larger page, and has been revised throughout, and contains many new illustrations.

ANNUAL REPORT (PART I.) FOR 1911-12 OF THE LOCAL GOVERNMENT BOARD.

THE first part of the forty-first annual report of the Local Government Board has recently been issued. Since 1907 these important Blue-books (which had previously appeared in a single bulky volume) have been issued in sections, greatly to the convenience of readers seeking information on particular groups of subjects.

Poor-law Administration and the Recommendations of the Royal Commission on the Poor-laws.

Part I., which is now before us, discusses the various details of Poor-law administration, and even a bare summary of these matters, though interesting, would be outside our scope. There are, however, two subjects which Mr. John Burns has treated with exceptional fulness, one of which relates to the altered conditions of medical relief, the other to the boarding-out of pauper children, both of which have a medical bearing. Moreover, the publication of the momentous reports of the Royal Commission on the Poor-law has invested with fresh interest whatever concerns the relief of the necessitous poor.

In a series of articles in THE LANCET of 1909[1] we discussed in detail the contents of the Majority and Minority Reports recently presented to Parliament. From a careful examination of the reports issued by the Board since that date, we gather that many of the weighty representations of the Commissioners have been treated by the department with the consideration to which they were obviously entitled. It was hardly to be expected that the President would promptly adopt those recommendations of the Minority Report which involve the unconditional transfer of the treatment of pauper sickness from the Poor-law to the public health authorities, although we believe that some such course will eventually be found to be the wisest, the most humane, and probably the most economical. The help required in [illegible] the community should be [illegible] of able-bodied destitution, [illegible] tail, directly or indirectly, the disability or disgrace ordinarily attaching to pauperism.[2] Already Parliament has indicated its partial acceptance of this principle by removing the disqualification for old age pensions which previously attached to receipt of relief from the rates. Mr. John Burns, in recording with satisfaction the substantial reduction of English pauperism in 1911 as compared with the previous year, attributes this state of affairs to the circumstance that from Jan. 1st of that year persons were no longer disqualified from becoming old age pensioners by reason of their having accepted Poor-law relief at some period since the beginning of 1908. He further states that, owing to the removal of this disqualification, a large number of persons had ceased to be chargeable to the guardians as paupers.

Altered Conditions of Medical Relief.

Although the total number of paupers in receipt of medical relief alone is not separately given, we learn that on the first day of last year 8061 men, 10,097 women, and 5250 children were receiving outdoor medical relief, as distinguished from other forms of so-called "public assistance." Of the indoor paupers on the same day 35 per cent. were under medical care in hospitals, infirm wards, or infirmaries. It is well known that the time-honoured "medical relief books" in use for Poor-law purposes are unsatisfactory, both for statistical purposes and as a means of recording particulars concerning the incidence and amount of pauper sickness. A new order was issued in 1911 establishing throughout England and Wales a uniform code of regulations governing relief. Among improvements of procedure we note the introduction of the "case paper system," the object of which is to secure to the guardians a complete knowledge of the circumstances of every applicant for relief. In the course of 1911 the Board issued special orders to certain of the metropolitan unions providing for the discontinuance of the medical relief book, and the substitution of "case papers" containing specified particulars as to the history, diet, and treatment of each case, the entries to be made by the responsible medical officer. Of this system, wherever it has been adopted, the reports are favourable. Thus, Mr. Gerald Hervey, H.M. Inspector, tells us, with respect to the Lowestoft Union, that "the case-paper system has worked extremely well, and from a financial standpoint has been a complete success." If the substitution referred to could be universally extended a valuable record of pauper sickness would shortly be available, which would materially advance the progress of preventive medicine.

Metropolitan Asylums Board.

The work of this institution is highly appreciated by Mr. John Burns, who claims its successful evolution as "an illustration of the applicability of the Poor-law to the demands of an increasingly complex civilisation, and of the advantages these attained in system and in economy." In criticism of this claim it should be remembered that the *personnel* of the [illegible] is altogether exceptional. The [illegible] the constitution of the aver[illegible] to be fairly comparable to that of the body in question would, we think, hardly be contended for by anyone. The report contains particulars of the accommodation provided for the treatment of sick children and of those suffering from ophthalmia, ringworm, and certain other diseases, as well as of the provision for open-air treatment of tuberculosis at Margate, Rutlington, and Carshalton.

Pauper Children: The Boarding-out System.

At the beginning of 1912 the aggregate of children under the care of guardians is stated to have exceeded 250,000. Of children supported in institutions to which paupers are admissible the number was 70,698, more than two-thirds of whom were fortunately housed in institutions other than workhouses or infirmaries. More than 10,000 outdoor pauper children were "boarded out," for the most part within the unions to which they are chargeable. In the present volume an interesting report appears from Miss Ina Stansfield, H.M. Chief Lady Inspector, from which it appears that by the end of the same year 540 boards of guardians had arranged for the supervision of boarded-out children, and that 98 salaried female visitors had been appointed to act under the instructions of the visiting committees which, to the extent of one-third, are composed of women. The difficulties of boarding out children within the districts to which they belong are once more forcibly illustrated by the experience of the year in question. The parents of such children are often undesirable, for they not only interfere with the children, but annoy respectable foster parents. It is remarkable how many parents or undesirable relatives manifest a sudden affection for their children immediately on their attaining a money earning age. They either entice them away from the custody of the guardians, or else, by their evil influence, counteract all the training the children may have received. The inspector recounts numerous instances of grave laxity on the part of those responsible for control of the conditions under which children are placed. These are often objectionable, and the frequent overcrowding of sleeping rooms is injurious both to health and to morals. Many of the conditions reported especially in respect of personal uncleanliness and the unwholesome sleeping arrangements of boarded-out children would have involved a public scandal had they occurred in a Poor-law institution.

Several instances are recorded where children excluded from school on medical certificate remain unprovided with the special treatment necessary for a cure. Among these are cases of mental defect, tuberculosis, anæmia, and epilepsy. The inspector judiciously remarks that unless children suffering in this way are promptly dealt with they are likely to be a long-standing charge on the rates, and also sometimes to act as centres of infection. It is not to the advantage of such children that they should be boarded out.

WORTHING HOSPITAL.—An anonymous gift of £1000 has just been made to the Worthing Hospital, and together with the legacy left by Alderman Cortis of £2000 the financial liability—except for upkeep and maintenance—in connexion with the new out-patients' department has been liquidated. The department is Worthing's memorial to King Edward.

NATIONAL INSURANCE IN ROUMANIA.

(From a Correspondent.)

Roumania has now joined the ranks of European countries which possess a system of compulsory insurance for the benefit of the working classes. The new Roumanian law is intended to regulate the position of workmen and artisans, and also to provide a system of small credit, while the second part of the measure is devoted to the introduction of a triple form of industrial insurance largely modelled on the German system. Three distinct forms of compulsory insurance are to be created—insurance against sickness, insurance against accidents, and provision for old age. The State is to bear the cost of administration, but will only contribute towards the cost of old age and disablement pensions.

Scheme of Insurance Against Sickness and Accidents.

Insurance against sickness will be compulsory for all workmen belonging to the various classes of occupation to be created by this law, and it is estimated that about 141,000 persons, including foremen, will fall within its scope and will become members of the one uniform sick club for the whole kingdom. The whole of the contributions will be defrayed by the insured, the employers being compelled to deduct the amount from each worker's wages weekly and stick a stamp of the corresponding value on his insurance card. The contributions vary according to the wages of the insured person, there being five different wage classes. The benefits promised are as follows:—Free medical attendance and free medicine in the case of sickness; from the third day of illness sick pay for a period not exceeding 16 weeks. In the case of heads of families the sick pay will amount to half the average wage of his class, or one-quarter of this amount should he undergo treatment in a hospital. At the death of an insured person his relatives will be entitled to a burial grant. In addition to the above direct benefits the wives and children of the insured are also entitled to free medical attendance, while maternity benefit, in the shape of free medical attendance and free medicine, will be given to the wives of insured persons. Disputes arising between the insured and the sick club are to be settled by a court of arbitration to be appointed in every district and consisting of three arbitrators—viz., one employer, one workman, and the chairman of the local law court.

The scheme of insurance against accidents is an almost exact replica of the German law. The owners of enterprises employing steam, gas, or electricity as a motive power, builders, owners of quarries, railways, mines, saw-mills, &c., form collectively an assurance corporation, including all their workmen, and the entire cost of this branch of insurance is defrayed by the employers, who contribute according to the number of employees, wages paid, and degree of danger of each occupation. In the event of an accident occurring to a workman in their employ, he is entitled to free medical attendance, and should he be entirely incapacitated for work a pension amounting to two-thirds of his earnings will be paid to him for life out of the common fund of the employers' association. Should he be quite helpless and require constant care, the pension may be so increased as to equal his full wages before the accident, while in the case of partial disability the amount paid out is to be correspondingly reduced. Should the accident lead to death, the relatives of the deceased worker are entitled to a burial grant of £4. The widow will receive a pension amounting to one-fifth of her deceased husband's average wage; another one-fifth is to be added for every child under 16 years of age for whom the widow has to provide.

Medical Treatment.

As regards the medical treatment of the insured, it must be borne in mind that in Roumania the entire cost of the upkeep of the hospitals, including the remuneration of their medical staff, is defrayed by the State, and that every person, regardless of religion or nationality, is entitled to free medical treatment in the hospitals, many of which were founded during the past century by wealthy boyars. It is in these hospitals that the insured will receive treatment.

In Bucharest a special organisation has been created for the medical treatment of the insured. The city has been divided into five districts, in each of which there are four doctors who have a purely consulting practice, the insured coming to them during certain fixed hours (two hours daily); in addition, three doctors are available in each district for visiting the insured in their homes, while the services of ten specialists, with fixed consultation hours, have also been secured. It is interesting to note that the list contains the names of no less than six women practitioners, entrusted with the treatment of female persons, out of a total of 35 "panel" doctors. These medical practitioners receive a monthly remuneration of from £8 to £10, regardless of the number of patients treated by each.

Contributions and Benefits.

The weekly contributions paid by the workers for insurance against sickness vary with the wage class to which the insured belongs, and amount to ½*d.*, 2*d.*, 3*d.*, 4½*d.*, and 6*d.*, according to the wage class. The sick pay amounts to 50 per cent. of the worker's wages, in the case of married men, and to 35 per cent. for bachelors. After confinement a female insured person receives sick pay during a period of six weeks. In the event of the death of an insured person his relatives are entitled to a burial grant ranging from £2 8*s.* to £4, according to the wage class of the deceased. Towards old age and invalidity insurance, worker, employer, and State each contribute weekly the sum of 1½*d.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,764 persons, 8672 births and 5886 deaths were registered during the week ended Saturday, Feb. 15th. The annual rate of mortality in these towns, which had been 17·0, 17·3, and 17·2 per 1000 in the three preceding weeks, was again 17·2 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 16·6 per 1000, or 0·5 above that recorded in London during the same period. The death-rates last week in the several towns ranged from 7·0 in Enfield, 7·4 in Southend-on-Sea, 7·9 in Bootle, 8·0 in Wallasey, and 9·0 in Wimbledon to 24·9 in West Bromwich, 25·0 in Swindon, 28·2 in Wigan, 29·4 in St. Helens, and 29·9 in Stockton-on-Tees.

The 5886 deaths from all causes in the 96 towns were 10 fewer than the number in the previous week, and included 458 which were referred to the principal epidemic diseases, against 430 and 445 in the two preceding weeks. Of these 458 deaths, 217 resulted from measles, 79 from infantile diarrhœal diseases, 70 from whooping-cough, 53 from diphtheria, 23 from scarlet fever, and 16 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3 per 1000, and coincided with that recorded in each of the two preceding weeks. The deaths attributed to measles, which had declined from 277 to 200 in the four preceding weeks, rose to 217 last week, and caused the highest annual death-rates of 3·0 in Stockton-on-Tees, 4·0 in Swindon and in Barrow-in-Furness, 5·2 in St. Helens, 6·3 in Wigan, and 7·5 in West Bromwich. The deaths of infants under 2 years of age referred to diarrhœa and enteritis, which had been 67, 65, and 75 in the three preceding weeks, slightly rose to 79 last week, and included 18 in London, 9 in Manchester, 5 in Birmingham, 4 in Portsmouth, 4 in Stoke-on-Trent, 4 in Liverpool, and 3 in Salford. The fatal cases of whooping-cough, which had been 81, 66, and 78, in the three preceding weeks, declined to 70 last week; 25 deaths occurred in London, 5 in Warrington, 4 in Liverpool, and 3 in Nottingham. The deaths attributed to diphtheria, which had been 47, 62, and 45 in the three preceding weeks, rose to 53 last week; 7 deaths were recorded in London, 4 in Birmingham, 4 in Bradford, 4 in Sheffield, 3 in Portsmouth, and 3 in Birkenhead. The deaths referred to scarlet fever, which had been 19, 17, and 29 in the three preceding weeks, fell to 23 last week, and included 3 in London, 3 in Manchester, and 2 in Brighton. The 16 fatal cases of enteric fever last week were equal to the average in the preceding six weeks; 3 deaths were registered in Stoke-on-Trent, 2 in Bolton, and 2 in Merthyr Tydfil.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospitals, which had steadily declined from 2112 to 1736 in the seven preceding weeks, had further fallen to 1701 on Saturday last; 196 new cases were admitted during the week, against 215, 209, and 209 in the three preceding weeks. These hospitals also contained on Saturday last 931 cases of diphtheria, 852 of measles, 320 of whooping-cough, and 40 of enteric fever, but not one of small-pox. The 1570 deaths from all causes in London were 71 in excess of the number in the previous week, and were equal to an annual death rate of 18·1 per 1000. The deaths referred to diseases of the respiratory organs, which had been 393, 447, and 373 in the three preceding weeks, rose to 443 last week, and were 3 in excess of the number recorded in the corresponding week of last year.

Of the 5886 deaths from all causes in the 96 towns last week, 214 resulted from various forms of violence and 511 were the subject of coroners' inquests. The causes of 42, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 56 other smaller towns. The 42 uncertified causes of death last week included 13 in Birmingham, 5 in Liverpool, 3 in Coventry, and 2 each in Southport, Blackpool, Sheffield, Sunderland, and Tynemouth.

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns, with an aggregate population estimated at 2,260,200 persons at the middle of this year, 1177 births and 883 deaths were registered during the week ended Saturday, Feb. 15th. The annual rate of mortality in these towns, which had steadily increased from 17·3 to 20·8 in the five preceding weeks, declined to 20·4 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death rate in these towns averaged 19·3, against a corresponding rate of 16·6 per 1000 in the 96 large English towns. Among the several Scotch towns the death rates last week ranged from 13·5 in Kilmarnock, 14·6 in Paisley, and 17·6 in Hamilton, to 25·2 in Dundee, 26·1 in Kirkcaldy, and 26·7 in Motherwell.

The 883 deaths from all causes were 17 fewer than the number in the previous week, and included 65 which were referred to the principal epidemic diseases, against 74 and 88 in the two preceding weeks. Of these 65 deaths, 39 resulted from whooping cough, 14 from infantile diarrhœal diseases, 8 from diphtheria, 3 from measles, and 1 from scarlet fever, but not one from enteric fever or from small-pox. These 65 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·5 per 1000, against 1·3 in the 96 large English towns. The deaths attributed to whooping cough, which had been 40, 55, and 52 in the three preceding weeks, declined to 39 last week, and included 20 in Glasgow, 4 in Motherwell, 4 in Falkirk, and 3 in Edinburgh. The deaths of infants under 2 years of age referred to diarrhœa and enteritis, which had been 20, 5, and 10 in the three preceding weeks, further rose to 14 last week; 6 deaths were recorded in Glasgow, 3 in Dundee and 2 in Greenock. The fatal cases of diphtheria, which had been 13, 6, and 12 in the three preceding weeks, declined to 8 last week, of which number 5 occurred in Glasgow. Of the 3 deaths attributed to measles, 2 were registered in Motherwell and 1 in Edinburgh. The fatal case of scarlet fever was recorded in Aberdeen.

The deaths referred to diseases of the respiratory system in the 16 Scotch towns, which had been 188, 221, and 214 in the three preceding weeks, fell to 192 last week; 31 deaths were attributed to different forms of violence, against 31 and 34 in the two preceding weeks.

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of this year, 635 births and 490 deaths were registered during the week ended Saturday, Feb. 15th. The annual rate of mortality in these towns, which had been 21·3, 20·4, and 20·9 per 1000 in the three preceding weeks, rose to 21·3 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death rate in these Irish towns averaged 21·3 per 1000; in the 96 large English towns the corresponding death-rate did not exceed 16·6, while in the 16 Scotch towns it was equal to 19·3 per 1000. The annual death rate recorded in the several towns last week was equal to 21·7 in Dublin (against 18·1 in London and 20·7 in Glasgow), 19·9 in Belfast, 29·2 in Cork, 19·1 in Londonderry, 17·6 in Limerick, and 26·6 in Waterford, while in the remaining 21 smaller towns the mean rate was equal to 20·7 per 1000.

The 490 deaths from all causes in the 27 Irish towns were 9 in excess of the number in the previous week, and included 35 which were referred to the principal epidemic diseases, against 30 and 41 in the two preceding weeks. Of these 35 deaths, 10 resulted from measles, 9 from infantile diarrhœal diseases, 6 from scarlet fever, 6 from whooping-cough, 3 from diphtheria, and 1 from enteric fever, but not one from small-pox. These 35 deaths from the principal epidemic diseases were equal to an annual death rate of 1·6 per 1000; in the 96 large English towns the death rate from these diseases did not exceed 1·3, while in the 16 Scotch towns it was equal to 1·5 per 1000. The deaths attributed to measles, which had been 17, 21, and 18 in the three preceding weeks, declined to 10 last week, and included 4 in Belfast and 2 in Newry. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 7, 5, and 9 in the three preceding weeks, were again 9 last week, and comprised 4 in Dublin, 4 in Belfast, and 1 in Londonderry. The 6 fatal cases of scarlet fever were 3 in excess of the average number in the six preceding weeks, and included 4 which were registered in Belfast. The 6 deaths attributed to whooping cough were slightly in excess of recent weekly numbers, and comprised 3 in Waterford, 2 in Dublin, and 1 in Belfast. The 3 deaths referred to diphtheria occurred in Dublin, Belfast, and Lurgan respectively. The fatal case of enteric fever was registered in Belfast.

The deaths referred to diseases of the respiratory system in the 27 Irish towns, which had declined from 135 to 104 in the three preceding weeks, rose to 115 in the week under notice. Of the 490 deaths from all causes, 147, or 30 per cent., occurred in public institutions, and 6 resulted from different forms of violence. The causes of 14, or 2·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

VITAL STATISTICS OF LONDON DURING JANUARY, 1913

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 5·3 per 1000 of the population, estimated at 4,518,191 persons in the middle of the year; in the three preceding months the rates were 6·8, 6·4, and 5·5 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Chelsea, City of Westminster, Stoke Newington, and Holborn; and the highest rates in the City of London, Bermondsey, Deptford, Greenwich, Lewisham, and Woolwich. Scarlet fever continued last month to show a declining prevalence; among the several metropolitan boroughs this disease was proportionally most prevalent in Stepney, Bermondsey, Battersea, Greenwich, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1717 scarlet fever patients at the end of last month, against 2242, 2250, and 2088 at the end of the three preceding months; the weekly admissions averaged 196 last month, against 303, 282, and 226 in the three preceding months. Diphtheria was rather more prevalent than it had been in the previous month; the greatest proportional prevalence of this disease was recorded in St. Pancras, the City of London, Poplar, Bermondsey, Greenwich, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 897, 917, and 959 at the end of the three preceding months, had declined again to 925 at the end of last month; the weekly admissions averaged 122, against 110, 124, and 120 in the three preceding months. The prevalence

*Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

of enteric fever showed a slight increase over that recorded in the preceding month, among the several boroughs this disease was proportionally most prevalent in Hampstead St Pancras, Islington the City of London, Shoreditch, and Bermondsey There were 37 enteric fever patients under treatment at the end of last month against 54, 42 and 37 at the end of the three preceding months, the weekly admissions averaged 7, against 7, 5, and 7 in the three preceding months Erysipelas was proportionally most prevalent in Shoreditch Bethnal Green Stepney, Southwark, Bermondsey, Deptford, and Greenwich The 28 cases of puerperal fever notified during the month included 4 in Stepney, 4 in Woolwich 3 in Chelsea, and 2 each in Islington Poplar Southwark, Bermondsey, and Wandsworth The 8 cases of cerebro spinal meningitis included 3 in Shoreditch 2 in Fulham and 2 in Hackney, of the 6 cases of poliomyelitis 2 belonged to Islington

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided, the death rates for all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs During the five weeks ending Feb 1st the deaths of 7319 London residents were registered, equal to an annual rate of 17 8 per 1000, in the two preceding months 15 5 and 12 5 per 1000 respectively The death rates last month ranged from 13 1 in Lewisham 14 1 in Wandsworth, 14 4 in Hampstead 15 2 in Fulham, 15 3 in Woolwich and 15 4 in Hackney, to 20 1 in Holborn, 20 3 in Bermondsey 20 4 in Kensington, 21 1 in Bethnal Green 22 6 in Finsbury and 26 0 in Shoreditch The 7319 deaths from all causes included 613 which were referred to the principal *infectious diseases, of these 305 resulted from measles* 24 from scarlet fever 42 from diphtheria 105 from whooping cough, 19 from enteric fever and 118 from diarrhœa and enteritis among children under two years of age The lowest death rates from these diseases was recorded in the City of Westminster, St Marylebone Hampstead Stoke Newington, the City of London Bermondsey, and Woolwich, and the highest rates in Hammersmith, Finsbury Shoreditch, Bethnal Green Stepney and Greenwich The 305 deaths from measles were 104 in excess of the corrected average number for the corresponding period of the five preceding years, this disease was proportionally most fatal in Finsbury, Shoreditch, Bethnal Green Stepney Poplar, and Battersea The 24 fatal cases of scarlet fever were 14 fewer than the corrected average number and included 3 in Hackney 3 in Islington 2 in Poplar 2 in Camberwell and 2 in Lewisham The 42 deaths from diphtheria were 37 below the corrected average number, of these 42 deaths 5 belonged to St Pancras 4 to Greenwich 3 to Islington 3 to Poplar, 3 to Lambeth, 3 to Deptford, and 3 to Lewisham The 105 fatal cases of whooping cough showed a decline of 26 from the corrected average number, this disease was proportionally most fatal in Paddington Hammersmith, Deptford and Greenwich The 19 deaths from enteric fever were slightly in excess of the corrected average number, and included 3 in Islington 2 in St Pancras 2 in Lambeth 2 in Wandsworth and 2 in Lewisham The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Hammersmith Shoreditch, Bethnal Green Islington Stepney Bermondsey and Camberwell In conclusion it may be stated that the aggregate mortality in London during January from the principal infectious diseases excluding diarrhœa was 4 9 per cent above the average

THE SERVICES

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel David V O Connell is placed on retired pay (dated Feb 13th 1913)

Major Charles W H Whitestone to be Lieutenant Colonel, vice D V O Connell (dated Feb 13th 1913)

The undermentioned to be Lieutenants (on probation) (dated Jan 24th 1913) —Sumner Hugh Smith Francis James Cairns Henry Beddingfield, Frederick Churchill Davidson, John Forbes O Connell William Ormsby Wyndham Ball (late Cadet, Dublin University Contingent, Officers Training Corps), John Crocket, Humfrey Newnham Sealy, John Rowe, Stanley Dermott Large (late Cadet, Edinburgh University Contingent, Officers Training Corps) Edward Charles Beddows, George Eldridge Dyas (late Cadet Inns of Court, Officers Training Corps), Arthur Hamilton Bridges, Conyngham Vernon Thornton, Cyril Helm (late Cadet, London University Contingent, Officers Training Corps), William Pennefather Croker (late Cadet, Dublin University Contingent, Officers Training Corps) Lieutenant Aubrey Gardner Brown (from the Royal Army Medical Corps Special Reserve), Percival Dillon Warburton, Robert Hemphill, and Albert Jackson

Lieutenant James B A Wigmore, from the Seconded List, is restored to the establishment (dated Feb 1st, 1913)

The undermentioned Lieutenants are seconded under the provisions of Article 300 Royal Warrant for Pay and Promotion, 1909 (dated Jan 24th, 1913) Francis J Cairns, George E Dyas, and Percival D Warburton

Surgeon General H G Hathaway has taken up duty as Deputy Director of Medical Services in India on transfer from the Half pay List of the Home Establishment

Lieutenant Colonel J B Wilson, senior medical officer and commanding No 29 Company of the Royal Army Medical Corps at Jamaica has been selected for the increased rate of pay under Article 317 of the Royal Warrant for Promotion Lieutenant Colonel B Forde has been transferred from the Aldershot Command to the Southern Command and appointed to the Salisbury Plain District to hold charge of the Military Hospital at Bulford Camp Lieutenant Colonel E Eckersley, lately Deputy Assistant Director General Medical Division War Office has embarked for a tour of service with the Southern Army in India Lieutenant Colonel M P C Holt, D S O Honorary Surgeon to the Viceroy and Governor General of the East Indies, has been granted an extension of *his command of the Station Hospital at Kasauli to September* next

Major J H R Bond has taken over charge of the Military Hospital at Naini Tal Major H M Nicholls has arrived home on leave of absence from India Major B R Dennis has been appointed for duty in the London District Major A R O Flaherty has left the Military Hospital at Devonport for a tour of service in India Major H K Palmer has joined at Aden Major W M Power has arrived home from Jamaica tour expired Major E P Connolly has been appointed to the Military Hospital at Rawal Pindi Cantonment Major E W W. Cochrane has arrived home, tour expired Major E McDonnell has been appointed for duty to the Eastern Command Major F W Begbie has taken over command of the Station Hospital at Kamptee Cantonment Major H Ensor, D S O has been appointed Registrar at the Royal Herbert Hospital Woolwich Major T H M Clarke C M G D S O, has taken up duty as Surgeon and Physician to the Royal Hospital at Kilmainham, Dublin, and Medical Officer, Royal Hibernian School Major R F M Fawcett on arrival in Ireland from Jhansi Cantonment India has been placed under orders for duty in the Dublin District

Captain C Scaife has been transferred from the Military Hospital at Colaba Bombay to Belgaum Cantonment Captain A A Sutcliffe has taken up duty at Newport on transfer from the Military Hospital at Chester Captain A Dawson and Captain V C Honeybourne serving at Aden, have been placed under orders for duty on board the transport s s *Rewa* which left Karachi for Southampton on Feb 12th with time expired troops Captain J C Hart has arrived home for duty from North China Captain J H Gurley has been selected for appointment as Specialist in Ophthalmology to the Royal Victoria Hospital at Netley Captain A S Williams has been transferred from the Military Hospital at Khanspur Murree Hills District to Nowshera Cantonment Captain F B Dalgliesh has taken up duty at the Military Hospital Jubbulpore Captain F D G Howell has arrived home from India for duty, tour expired Captain C Kelly has been appointed to the Eastern Command Captain H S Dickson has arrived home on leave of absence from Gibraltar Captain A E S Irvine has embarked on board the transport s s *Rohilla* for duty on the voyage to South Africa and back Captain C H O Rorke has been transferred from the Military Hospital at Roorkee to Allahabad Cantonment for duty Captain J B Hanafin has taken up duty at the Military Hospital, Nowshera, on transfer from Peshawar Cantonment Captain J C L Hingston has been placed under orders for transfer from the Ninth (Secunderabad) Division of the Southern Army in India to Burma, and on arrival will be appointed Specialist in Dermatology and Venereal Diseases to the Burma Division. Captain J. A. Renshaw has been granted six months' leave of absence home from India. Captain J. F. Granted has taken up duty as Specialist in Electrical Science to the Burma Division at Headquarters, Maymyo Cantonment. Captain L. Wood has been appointed to hold charge of the Military Hospital at Hyderabad, Sindh. Captain A. S. Littlejohns has arrived home for duty from South Africa, tour expired. Captain J. J. O'Keefe, on arrival in India for a tour of service, has been appointed to the Seventh (Meerut) Division of the Southern Army. Captain F. Forrest has joined the Irish Command. Captain A. R. Wright has arrived home on leave of absence from the Military Hospital at Malta. Captain G. P. A. Bracken has been granted six months' leave of absence home from India. Captain E. C. Caddell has taken up duty at Brigade Headquarters, Karachi, as Specialist in charge of the Bacteriological Research Laboratory.

Lieutenant J. S. Levack has been transferred from the Military Hospital at York to Bradford for duty. Lieutenant W. T. Graham has taken up duty at the Military Hospital, Tidworth, Salisbury Plain, on transfer from Durrington. Lieutenant P. Hayes has embarked for a tour of service in India. Lieutenant W. L. Webster has been transferred from Kilworth Camp to Limerick.

INDIAN MEDICAL SERVICE.

Colonel R. B. Roe has taken up duty as Assistant Director of Medical Services to the Sirhind and Jullundur Brigades, Third (Lahore) Division, in succession to Colonel R. W. S. Lyons, transferred to Divisional Headquarters.

Lieutenant-Colonel R. H. Castor has arrived home on leave of absence from India. The services of Lieutenant-Colonel W. D. Sutherland have been placed temporarily at the disposal of the Government of Bengal Presidency for employment on special duty at the Medical College, Calcutta. Lieutenant-Colonel J. C. Hulbert has been transferred from the Central Research Institute at Kasauli on completion of special duty to Mutha. Lieutenant-Colonel H. S. Wood, civil surgeon at Rajshahi, has been granted privilege leave of absence.

Major W. R. Battye, residency surgeon at Mewar, has been granted privilege leave of absence. Major T. Jackson has been selected for appointment to the Medical Council in Bombay. Major H. Ainsworth, on return from furlough, has taken up duty as Professor of Ophthalmic Surgery at the Government Medical College, Lahore, relieving Lieutenant-Colonel E. V. Hugo of the additional charge. Major G. Browse has been granted an extension of his leave of absence home from India by the Secretary of State. Major C. H. Watson has taken up duty as Staff-Surgeon at Headquarters of the Derajat Brigade. Major S. H. Burnett has been selected for appointment as Superintendent of the Lunatic Asylum at Colaba, Bombay.

Captain D. G. R. S. Baker has been appointed Specialist in Ophthalmic Surgery. Captain F. C. Fraser has taken up duty under the Civil Administration in Madras Presidency. Captain C. H. Barber has been granted one year's extension of leave of absence on medical certificate. Captain S. H. Middleton West has arrived home on leave of absence from India. Captain R. T. Wells has taken up duty as Superintendent of the District Jail at Dera Ghazi Khan, in succession to Captain H. C. Keates. Captain N. W. Mackworth, officiating civil surgeon at Purnea, has been granted privilege leave of absence combined with study leave and furlough home from India for 15 months. Captain A. N. Thomas has been appointed to the substantive medical charge of the 105th Mahratta Light Infantry. Captain F. A. Barker has joined the Jail Department in the Punjab for temporary duty. Captain W. D. Keyworth has taken over officiating medical charge of the 110th Mahratta Light Infantry. Captain W. T. Finlayson has arrived home on leave of absence from India. Captain A. M. Jukes has taken up duty as officiating Deputy Sanitary Commissioner in the Metropolitan Circle, Calcutta. Captain N. M. Wilson has taken up duty as Plague Medical Officer at Shahpur. Captain J. M. A. MacMillan, civil surgeon at Hoshangabad, has been transferred temporarily to Jubbulpore on relief by Captain E. P. Wernicke.

Lieutenant V. P. Norman has been granted six months' extension of his leave of absence home from India on the recommendation of a medical board.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain Wilson Ranson is seconded for service with the Territorial Force (dated Feb. 8th, 1913).

The undermentioned Lieutenants to be Captains (dated Feb. 11th, 1913): William Darling and John M. Darling. The undermentioned Lieutenants are confirmed in their rank: Henry B. Parker and Robert D. Goldie.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Notts and Derby Mounted Brigade Field Ambulance, Royal Army Medical Corps: The undermentioned officers, from the list of officers attached to units other than medical units, to be Captains (dated Feb. 15th, 1913): Captain Alexander Tydd Mulhall and Captain Francis Raymond Mitchell Heggs.

Supernumerary for Service with the Officers Training Corps.—Lieutenant (Provisional Captain) Robert Davies-Colley (serving with the University of London Contingent, Senior Division, Officers Training Corps) resigns his commission (dated Feb. 19th, 1913).

For attachment to Units other than Medical Units.—John Orlando Summerhayes (late Lieutenant, 4th Battalion, The Oxfordshire and Buckinghamshire Light Infantry) to be Lieutenant (dated Feb. 8th, 1913).

Major R. J. Blackham, R.A.M.C., who has been associated with Colonel Roberts, I.M.S., in the treatment of His Excellency the Viceroy of India since the outrage at Delhi on Dec. 23rd, has been appointed Honorary Surgeon on His Excellency's Personal Staff.

Correspondence.

"Audi alteram partem."

WEISMANN AND LAMARCKISM.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 30th last there is a statement to the effect that Dr. A. M. Gossage at a meeting of the Harveian Society on Nov. 21st, read a paper on Heredity, in which the assertion was made by him that "Lamarckism, or the inheritance of acquired characters, must be regarded as disproved by the work of Weismann." But is that really so? and is the assertion by Dr. Gossage the result of an investigation by him of the teachings of Lamarck, or is it an assertion based on the *ipse dixits* of sundry biologists who fail to recognise the true teachings of Lamarck? I raise the question since I feel assured that to the physician will fall the duty, not alone of demonstrating the truths of Lamarckism, but also of bringing out of chaos the true factors at work in organic evolution and in heredity. Undoubtedly the work of Weismann is most important, since to him fell the rôle of demonstrating, once for all, how heredity is carried on and maintained in the organic world. But far from disproving the transmission of acquired characters, his work really cleared the way for the true understanding as to why and how acquired characters are transmitted.

What did Weismann really do? Following the suggestions of Nussbaum, he laid the foundation of his fame by demonstrating the continuity of the germ-plasm. He proved how, after division and subdivision of the zygote or fertilised egg, a colony of cells is formed out of which one only of the colony ultimately develops into a new organism; the other cells of the colony remaining undeveloped, constituting the germ-plasm, which becomes, in time, the sexual cells of the fully developed new organism. Hence the new organism becomes, as it were, a brother or sister of the previous organism, and not a son or daughter. This is, as I have said, the theory of the continuity of the germ-plasm on which the real fame of Weismann rests, and when we fully understand the process, we begin to realise the wonderful provision made by nature in order to secure that heredity shall be a process of true repetition of necessary characters. But Weismann, not content with demonstrating the continuity of the germ-plasm, went further and maintained that the germ-plasm was inviolable—i e, that it was impossible for it to be influenced or affected by any means In order to justify his position he was forced to postulate the theory that variations arose not alone through a mixing of the germ plasms of germ and sperm, but also that the inviolable germ plasm was imbued with an intrinsic power to vary *per se*—i e, that there was an inherent power within it rendering it capable of throwing out indefinite variations of varying qualities On that assumption he postulated the theory of the all sufficiency of natural selection Subsequently, however, he was forced to admit through the results of experiments by others that the germ plasm was not inviolable, but that it could be influenced by certain conditions in the environment That the germ plasm and its developments can be directly acted on by adverse conditions in the environment has been quite recently shown by Professor Adami in your pages Professor Adami brought together overwhelming evidence that alcohol other poisons, &c, do adversely influence the germ plasm and its developments A careful study of Professor Adami's address on Eugenics unto the Third and Fourth Generation will well repay any physician for his trouble

It will thus be seen that the difference between Lamarckism, or the theory that acquired characters are transmitted, and Weismannism resolves itself really into a question of degree, especially as regards direct influences It is most important to recognise that fact since the Lamarckian [illegible] tinuity of the germ [illegible] of the individual i[illegible] ut not always an exact repetition, since the living organism is capable of being modified through the changing influences of the environment, which influences if permanent are gradually transmitted and must appear even if unrecognisable, in the ontogeny Now although the direct injurious influences are transmitted through individuals as proved by Professor Adami there is no doubt that the direct inimical influences are in the long run, as seen in racial survival counteracted by an indirect reaction of a beneficial nature This is clearly seen as regards infectious diseases, adverse conditions of life, as in city life and is clearly demonstrated in the Styrians, the arsenic eaters This racial survival through adaptation is attributed to natural selection by an eminent writer Dr Archdall Reid But its explanation is far easier to the physician by recognising the fact that all living bodies in the presence of continuous inimical influences tend to protect themselves by elaborating an antidotal principle which ultimately by the educability of the cells, serves to prevent extinction and thus to lead to survival of a race There is a tendency amongst biologists to belittle the opinions of those who have not been trained in biological laboratories Such disparagement should however, have no influence in deterring physicians from studying the questions involved, since the very nature of their training and life work enables them to grasp facts relating to the living body

Biologists have become buried in the great accumulation of biological facts hence what is required is that any competent to do so should arrange and rearrange such facts and coordinate them with a theory by which all can be explained That can be done I hold by the theory that functional adaptation is brought about through the inheritance of acquired characters Perhaps it is well to draw Dr Gossage's attention to the fact that Nussbaum, who first formulated the theory of the continuity of the germ plasm regarded it as in no way militating against the theory of the transmission of acquired characters It was Weismann's strong belief in the factors of natural selection that misled him into believing that the continuity of the germ plasm is wholly operative against the transmission of acquired characters —I am, Sir, yours faithfully,

Barbados Jan 20th, 1913 R F LICORISH M D

DERMOIDS OF THE KIDNEY

To the Editor of THE LANCET

SIR,—In THE LANCET of Feb 8th I notice a clinical lecture by Mr Jocelyn Swan on renal tumours in the course of which he says "There have been recorded only two cases of dermoid of the kidney

It is quite true that even in the latest monographs on renal tumours little or no reference is made to the occurrence of dermoids in this organ and by some authors their occurrence here is denied As, however, I know of several cases besides those instanced by Mr Swan, it seems desirable that pointed reference should be made to this matter, with the view of clearing up erroneous beliefs in the contrary sense which have an important bearing on the pathogenesis of dermoids in general For instance, it has been alleged that dermoids are never found growing primarily from any part or organ of the abdomen save the ovary and on this erroneous basis ovarian dermoids have been presumed to be quite different in origin from dermoids in general

Another point which merits attention in this connexion is Paget's case of renal dermoid Most authors who have cited this case have like Mr Swan referred to it as a human specimen whereas it is from a sheep The specimen is in the Royal College of Surgeons Museum (No 1904 of the pathological series) a piliferous dermoid embedded in a mass of fat which had replaced one of the kidneys of which there was no trace Other cases of renal dermoids besides the Haeckel Wedemann one referred to by Mr Swan have been recorded by Gol[illegible] Rider Thompson[2] and Madelung Schlegtendal[3] [illegible]

In Goldsmith's case the dermoid was subcapsular and intimately blended with the upper pole of the right kidney It was piliferous and comprised a tooth In the Madelung Schlegtendal case the calcified dermoid seemed to occupy the place of the right kidney, of which the only trace discoverable was a thin layer of its substance blended with the cyst wall In the Rider Thompson and Haeckel Wedemann cases the dermoids seem to have been let into the renal substance in the vicinity of the renal pelvis The contents of the former tumour comprised neuro epithelial cerebral like substance and bone while the latter was simply piliferous Wyss met with a dermoid cyst of the kidney with ossified walls which had replaced nearly the whole kidney, only some remains of its upper and lower poles being recognisable The cyst contained masses of cholesterine

Besides such cases as the foregoing I know of several instances of dermoids situated in the extraperitoneal tissues in the immediate vicinity of the kidney In Ruge's case the left kidney was in close touch with the inner side of a cyst of this kind and in Zweifel's case the dermoid was intimately connected with the top of the left kidney which it had displaced into the pelvis Both of these cysts besides their pultaceous contents were also piliferous and enteroid cysts were associated [illegible] rdenheuer's case the dermoid lay [illegible] in its wall teeth bony fragmen[illegible] A retroperitoneal paranephritic dermoid cyst of the simplest type was intimately blended with the capsule of the kidney in Czerny's case, and Ehler's remarkable conglomerate of four dermoids was situated over the hilum of the left kidney

I am Sir yours faithfully,

Walton by Clevedon Feb 14th 1913 W ROGER WILLIAMS

TOXIC SYMPTOMS ARISING DURING THE USE OF NOVOCAINE

To the Editor of THE LANCET

SIR —In view of the well merited favour which novocaine now enjoys as a local anæsthetic it may be not without interest to record two cases in which alarming symptoms developed during the course of its administration These both occ[illegible] artment of the Roy[illegible] I was connected, [illegible] permission of Mr E Scott Carmichael who was in charge at the time

CASE 1 —The patient a stolid, hearty man 43 years of age, a weaver by trade came in order to have two sebaceous cysts removed from the under surface of the chin immediately below the lower margin of the mandible and slightly to the right of the middle line He declared that, apart from this condition he had never had any trouble in his life and subsequent examination confirmed this by revealing a perfectly normal heart and vessels healthy kidneys and the remaining systems apparently equally efficient No nervousness whatever was shown as he took his place on the table and the assurance was smilingly given that the prick of the needle was hardly felt Two drachms of a 1 per cent solution of

[3] Archiv für Klinische Chirurgie Band lxxxvi 1837

novocaine, equivalent to slightly more than one grain of the solid drug, and containing not more than three-quarters of a minim of 1 in 1000 solution of adrenalin hydrochloride, were then slowly introduced. The injection was made in the usual manner, the needle being inserted just below the skin and gradually withdrawn as the fluid was expelled. During this process, which occupied approximately three minutes, the patient remained placid and unmoved. Then, without the slightest warning, the pupils became widely dilated and fixed, consciousness had completely gone, and a cold, clammy sweat burst out upon the face. Both the breathing and the pulse were slow, the former shallow and scarcely audible, the latter thready and irregular. The whole body became markedly rigid. In this state he remained for fully a minute, the bodily rigidity continuing as a prominent feature. Then the pupils were seen to contract slightly and to pass into a state of hippus, the muscles relaxed, and consciousness was recovered with a start that nearly carried the patient off the table. The pulse, although its rate remained as low as 55 per minute, regained its amplitude and force. The temperature was found to be subnormal—97·6° F. The cysts were now removed, efficient anæsthesia having been produced by the injection. During the operation, however, the patient experienced great nausea and a feeling as if he were "going off again," as he himself expressed it. The face remained pale and covered with beads of clammy perspiration. Strychnine hydrochloride, 1/60th of a grain hypodermically, and 4 drachms of brandy by the mouth hastened recovery, and in the course of an hour, with the exception of slight weakness and continued nausea, he was quite himself again.

In connexion with the above symptoms other possible causes suggest themselves, and must as far as possible be excluded before we can attribute the blame to the absorption of the drug. Thus, mere fright, which in a highly strung patient might be accounted a sufficient explanation, seems here to be out of court when one considers the disposition of the patient and the prolongation of the collapse. Pain could hardly be held as responsible, as the patient made the positive statement that he felt no pain or discomfort; and that, immediately before consciousness was lost. Lastly, it would be difficult to believe that the minute quantity of adrenalin present could have caused such far-reaching effects.

CASE 2.—This case, that of a male aged 44, I shall not emphasise. A musician by profession, the patient's nervous disposition made it difficult to judge how far his symptoms were due to his nervousness and how far to the anæsthetising drug. The same quantity of novocaine in the same strength of solution as in Case 1 was injected into the base of the right index finger for the removal of a painful nail. Shortly after the introduction of the fluid he had an attack of syncope with collapse and subsequent vomiting. I am inclined to think, from the delayed onset, the subsequent vomiting, and the long continuance of the symptoms, that the novocaine had at least some share in their production.

Such cases as those recorded above must be comparatively rare. In our own department the drug was widely used every day, and I have observed no others similar to them; nor has any case been recorded within my knowledge in the English literature at any rate, since the use of novocaine as a local anæsthetic originated in Germany about the year 1905. The possibility that some persons may have an idiosyncrasy towards it is thus suggested. It may be of interest in passing to point out that in 1910[1] Major Gabbett recorded a case of death under spinal anæsthesia, induced by novocaine, in which, as in the first case recorded in this paper, rigidity of the body and limbs was a marked feature.

Again, the contingency of the solution being injected directly into a small vein, especially in such a vascular region as the head and neck, must not be overlooked; but the precaution taken of gradually withdrawing the needle as the injection was made rendered it unlikely in our cases. Lastly, the nature of the solution of novocaine falls to be considered. Most writers are of the opinion that aqueous solutions of the drug may be boiled repeatedly and kept for long intervals without any degeneration or hydrolysis taking place. As used in the Royal Infirmary, 2 per cent. solutions are carefully prepared in the infirmary laboratory and sent up in sterile flasks for use in the wards. These are diluted to the requisite strength with normal saline just before use. Although the method of preparation is uniform, the efficiency of the drug as an anæsthetic appears to vary from time to time, and not only so, but in some solutions a yellow tinge becomes perceptible after one or two boilings. This was noted by Lemaire.[2] The writer advises that such solutions should be discarded as being irritating to the tissues. Is it not possible that what is irritating locally might be toxic when absorbed into the general circulation? Of course, the rarity of toxic symptoms in the use of the drug shows that the formation of nocuous products is of by no means common occurrence; yet I think that the possibility of their being present and the conditions under which they are formed are subjects worthy of further investigation. In the solution used in Case 1 there was a distinct yellow tinge, and since our unpleasant experience there we make a point of discarding all preparations that are not perfectly clear.

I am, Sir, yours faithfully,

R. CAMPBELL BEGG, M.A., M.Sc., M.B., Ch.B. Edin.,

ARTIFICIAL RESPIRATION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 1st, p. 345, Professor Leonard Hill asks why mouth-to-mouth artificial respiration is not called "Elisha's method." I may state that in many parts of the United States of America, especially New York, it is so called. In the Sloane Maternity Hospital there, one of the finest maternity hospitals in the world, the method is used considerably when the need for it arises. Of course, it is used elsewhere for patients other than the new-born. In a paper in course of preparation I discuss various practical methods of starting the new-born non-breathing child to normal respiration. It might not be out of place here to give the Elisha method as applied to the new-born.

In the Elisha method a towel is placed around the feet to prevent slipping, and the child is held upside down. A little piece of gauze wrapped on the little finger clears the mouth and throat of any mucus or other material. The child is then placed on its back on a table, a piece of gauze put over its mouth, and the legs are bent up so that the knees are pressed into the pit of the stomach to prevent its being blown up. The other hand is placed under the head, neck, and shoulders. The mouth of the person holding the infant is placed over its mouth, and one blows carefully a moment. Usually the chest of the babe can be felt to fill. Then bend the head and shoulders forwards so as to drive out the air. Repeat at the rate of about 15 times to the minute, and after a few times see if the child will start for itself. It is wonderful how a few breaths like this will turn a purple baby pink. Then if it does not start, blow on its stomach, turn it upside down again, and spank the bottom of the feet or buttocks. Flick a little cold water on to the abdomen, warm and cold tubbing, and if it gets blue again repeat the Elisha method. The combination usually starts the baby. I have helped do these methods for two hours and been rewarded by the child starting itself at the end.

I agree with Professor Hill that the credit ought to go to the originator, and in spite of any other names that may be applied to this procedure I think that none will claim priority. I am, Sir, yours faithfully,

Toronto, Canada, Feb. 3rd, 1913. GORDON G. COPELAND.

TREATMENT OF BOILS, CARBUNCLES, &c., BY SULPHURIC ACID.

To the Editor of THE LANCET.

SIR,—About four years ago Dr. J. Reynolds and Dr. Russell J. Reynolds, in a short note, drew attention to the treatment of boils, carbuncles, and other troubles due to staphylococcic invasions by the internal administration of sulphuric acid in 20 minim to 30 minim doses, well diluted, every 4 hours.

Since reading that note I have employed no other remedy in the treatment of boils and carbuncles, excepting protective dressings, and have experienced most gratifying results, without exception the condition has quickly improved in those cases where suppuration had been well established, and it has not failed to abort commencing mischief or secondary crops My thanks are due to the authors for bringing their treatment to my notice

---

[1] Brit. Med. Jour., March 19th, 1910.

[2] Repertoire de Pharmacie, September, 1906.

Recently I adopted this treatment in a case of severe acne, the drug effected a rapid improvement and acted better than any remedy that had been employed in this case during a period of 35 years In the case of a morphia habitué, who when he came under treatment had threatening abscesses on both arms, due to the injection of septic solutions of morphia, I employed this remedy with the usual satisfactory results so far as the inflammatory conditions were concerned At the same time there was a vast improvement in the condition of the gums, which were affected with extensive pyorrhœa alveolaris Both the patient (who was *a medical man*) and I were *inclined to ascribe this decrease* of oral sepsis to the sulphuric acid I recall another morphia case, where the arms, legs, chest, and abdomen were covered with scars of a keloid character due to old injection abscesses, in which there occurred intense itching After trying many drugs in vain, as there were a few pustules, I gave sulphuric acid, and the patient received immediate relief In this case I have just heard that the irritation has returned a few weeks after treatment was discontinued

I have but few opportunities here to treat ailments caused by staphylococcic infection Still, my experience, though limited, leads me to believe that this method of treatment would be largely employed if more generally known, and it is *to be hoped that its original* authors *will publish a further* and more extensive account of the results which they have obtained

THE ABDOMINO-PERINEAL OPERATION FOR RECTAL CANCER A SUGGESTION FOR REDUCING THE MORTALITY.

To the Editor of THE LANCET

SIR,—It is now generally recognised that the surgeon operating for cancer is not doing his duty to his patient unless he removes the diseased area as widely as is compatible with safety to life The abdomino perineal operation has been evolved to meet this axiom, and from the point of view of permanent results has an excellent record but unfortunately there is attached to it an appalling mortality from something over 20 per cent in selected cases (women under 60 being the best subjects) to probably nearly 40 per cent

The causes of the mortality are chiefly sepsis and shock, embolism also must be mentioned, Shock can be met by the usual treatment, which at present we do not know how to improve, but in the matter of preventing sepsis I think more can be done I performed *this operation some two years ago* in conjunction with another general practitioner on a man aged 60 There was no shock and the patient appeared to do well for three days, but expired on the fifth day from toxæmia generated in the pelvic tissues I then came to the conclusion that this patient would have had a much better chance of surviving if he had had his bowel cleaned out before operation, and determined if it ever fell to my lot to perform this operation again to do a preliminary colotomy and wash out the bowel for a fortnight with antiseptics

I would suggest that a [illegible] should be adopted as a rout [illegible] advantages Firstly, with [illegible] *periods*, at any rate, of intestinal stasis when the bowel is full of fluid, evil smelling fæces teeming with pathogenic microbes and toxins, the latter being absorbed by the bowel and poisoning the whole system A colotomy would allow free drainage and get rid of the poisoning, and the patient would have a fortnight with good appetite, &c, and would undoubtedly at the end of that time be in a better plight for undergoing a severe operation Secondly, the washing out of the bowel would, apart from clearing away all fæcal material and the bulk of the organisms, clean up the surface of the growth, and, as constant reinfection of the growth if ulcerated would be absent, any glands that might be enlarged from sepsis would subside Also inflammatory thickening round the growth would subside, and at the second operation, which in a doubtful case might be exploratory, the freedom from inflammation might make a growth operable which otherwise would have appeared inoperable *Again, at the second operation any organisms that* might have been in the lymphatics or perirectal tissues would have been destroyed or rendered immune in the course of a fortnight, and so only healthy tissues would be cut through, and another source of infection eliminated Thirdly, the operation itself would be much shortened, as the surgeon would be operating on collapsed clean bowel instead of bowel full of filthy fæcal matter Time would be saved, too, in that instead of having to perform a colotomy through a stab wound in the inguinal region, he would only have to close the upper end of the divided pelvic colon by a purse string suture or two Again, knowing that the rectum was clean and empty, no time need be *wasted in elaborately closing the anus before starting* the perineal part of the operation To sum up, the perineal operations, though safe, have very bad results as regards recurrence The abdomino perineal is a scientific operation, and the late results in those cases that survive are excellent, but the immediate mortality is great and is largely due to sepsis Can these deaths due to sepsis be avoided or largely reduced by a preliminary colotomy and antiseptic douches?

I am, Sir, yours faithfully,

Great Yarmouth, Feb 14th, 1913

THE SERO-DIAGNOSIS OF PREGNANCY.

To the Editor of THE LANCET

SIR,—For some months past we have been engaged in investigating in these laboratories (Director, Professor R T. Hewlett) the value of the sero diagnosis of pregnancy, evolved by Abderhalden in accordance with his hypothesis of the protective *ferments* *Up to the present we have been* working mainly with the dialysis method, and we are able to confirm Abderhalden's results in so far as we have always obtained positive tests with sera of pregnant cases Our excuse for troubling you with this letter is, that in the course of our experiments we found that these ferments were not necessarily tissue specific because normal uterine tissue gave a positive reaction, and whilst our observations were made early in January we find that Dr Paul Lindig, of Jena has published the results of his observations in the *Munchener Medizinische Wochenschrift* of Feb 11th, 1913, No 6, p 290, which are identical with ours There is, however, this difference in the investigations carried *out* by Dr Lindig and ourselves in that we have tested a much larger number of normal controls At the same time we made some polariscopic observations (Abderhalden's optical method) with placental peptone prepared by ourselves, but it is too early at present for us to come to any definite conclusions as to the clinical value of the optical method, but we hope shortly to publish our complete results

We are Sir, yours faithfully,

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET

SIR,—The matter of voluntary payments to panel doctors by insured persons requires more attention

As a considerable number of insured persons are desirous of ignoring the medical benefit provisions of the National Insurance Act, and have intimated to their doctor that they wish to be attended by him in the ordinary way, in spite of the fact that he has accepted them as panel patients, I have taken legal opinion on the following question, and have received the reply which is given below

Question—Is it open to a practitioner on the panel to receive payment voluntarily made for treatment (such treatment being within the competence of a general practitioner) rendered to an insured person under his care, such an insured person not being a person who has made his own arrangements in the manner provided by the Regulations?

Answer—As the Regulations stand I think it is open to a practitioner on the panel to receive voluntary payments for treatment within the competence of a general practitioner.

I am, Sir, yours faithfully,
Rochdale, Feb. 18th, 1913. J. CUTHBERTSON WALKER.

To the Editor of THE LANCET.

SIR,—With all the respect due to one who has been in the profession three times as long as I have, I maintain that Dr. George C. Crichton lays himself open to the charge of having allowed the wish to be father of the thought. The actual state of affairs is that the majority of practitioners in London at any rate repudiate the right of the British Medical Association (or rather its provincial majority) to rescind or abrogate the pledge. This pledge was given by each signatory in the terms that all service under the Act is to be refused until the terms and conditions of such service shall be satisfactory to the whole profession. It is therefore undoubtedly as binding now as ever it was upon every man and woman who has at heart the scientific and economic interests of our profession and the real improvement of the public health. The panel system is still officially branded with the stigma of being "derogatory" to those who serve under it, and it is merely glossing the facts and hiding the truth to pretend that it is not also "dangerous to the public health." For these reasons it is evident that no action by the British Medical Association can ever bring about a fusion between the two present (and, I fear, future) classes of doctors, the Independents (or "Die-hards") and the Panellites. I am, Sir, yours faithfully,
Brixton-hill, S.W., Feb. 17th, 1913. DONALD J. MUNRO.

THE ALL-INDIA SANITARY CONFERENCE.

(FROM OUR OWN CORRESPONDENTS.)

(Concluded from p. 488.)

Sewage and Refuse Disposal.

THE afternoon of the fourth day was devoted to sewage and refuse disposal, and much interesting matter was forthcoming, including the use of small incinerators and destructors.

Major F. H. HUTCHINSON, I.M.S., gave the results of the Poona experimental sewage installation.—Mr. C. L. COX described the Colombo drainage scheme and sewage treatment.—Major S. A. HARRISS, I.M.S., in a paper on Night Soil Disposal and associated Fly Breeding, raised the following points: 1. What is the best method of excreta disposal in towns to prevent fly-breeding in night soil (*a*) in a colloid condition, and (*b*) in a solid condition, from private latrines, having regard to probable expense and income to the municipality, and the possibility or impossibility of irrigation of trenched land? 2. Howard has shown that flies can come to the surface through 48 inches of sand. In these circumstances how can night soil best be disposed of to prevent fly-breeding at fairs, having regard to (*a*) expense, and (*b*) fluctuating population, which may reach 2,000,000 a day?—Dr. W. R. MACDONALD, health officer of Madras, gave his results with small incinerators in Madras, and members of the conference had an opportunity to inspect the results, which were excellent. Dr. Macdonald warned against the use of night soil. An interesting discussion took place.—Dr. A. G. NEWELL said he had seen nearly all the different types of incinerators, and considered they had effected a financial saving, being useful in filling up low-lying land. Those in Madras were for the burning only of rubbish free of night soil and gave good results.—In reply to Major WILLIAMS, who said the Burmese objected to the smell of burning, Dr. MACDONALD said he had had only 12 complaints out of a population of over 500,000.—Dr. T. M. NAIR said that there was a distinct prejudice against the burning of night soil. The success of incinerators depended on the separation of the night soil from rubbish.—In reply to Dr. MASTER, Dr. MACDONALD said that the maximum time of storage prior to incineration was 25 hours. There arose no question of congestion of rubbish in the dry season.—Major WILLIAMS said a temperature of 2000° F. was necessary to prevent nuisance, for the smell of slow combustion might be carried half a mile or more.—Colonel WILKINSON, I.M.S., said that combustion should be exceedingly slow to minimise nuisance from smell, and instanced the boiling of milk over a slow fire as contrasted with the smell from burning of milk. He suggested gradation in incinerators with night soil on top. It was said that it was morally wrong to deprive the soil of refuse and night soil, but the municipality saved by incinerators the cost of cartage. In the absence of sewers he regarded the incinerator as the best method of dealing with night soil.—Captain W. C. ROSS thought incineration of rubbish very easy and that of night soil very difficult. They could not be discussed together.

Major HARRISS read a paper on the Sullage Farm at Agra to show that sullage farms when properly run are paying concerns, and form a useful adjunct to schemes for the improvement of the milk-supply.

Infiltration Gallery at Conjeevaram.

On the fifth day 25 delegates went to Conjeevaram to inspect the infiltration gallery. Conjeevaram is a town 45 miles south-west of Madras, in the valley of the river Vegavati. At the site of this town this river is 1000 feet wide, although its source is only some nine miles distant, and it possesses a deep sandy bed. Flood water is rarely seen in the river, and the quantity is small. The river water has the reputation of flowing underground through the sandy bed, and thousands of acres of paddy are cultivated by spring or surface channels excavated therein. The works consist of a gallery in the river bed and a pumping station. The gallery is 550 feet long, and consists of four rows of open-jointed 9-inch stoneware pipes, surrounded by broken stone filling to a depth of 7 feet, of which 6 inches are below the barrel of the pipes. The bottom of the gallery is fixed at a depth of 20 feet below the river bed at the left bank of the pumping station. The broken stone is of 1½-inch size. The four rows of pipes terminate in a well on the river bank. From this well the water is conducted through a cast-iron pipe to the suction well, the end of the pipe being provided with a reservoir sluice, so that ingress of water into the suction well can be cut off when this well requires examination. The suction well is 10 feet in diameter.

Milk-supply.

On the sixth day the problems connected with the milk-supply were discussed in four papers. The first was that on the Utilisation of a Continuous Temperature of 50° C. for the Preservation of the Potability of Milk, by Military Assistant Surgeon MACKEY, who stated that the temperature of 50° C. was on the border line between an incubating temperature (30-40° C.) and a sterilising temperature. Organisms did not multiply at this temperature and in time were actually killed. The method was simple, since it could be carried out by a small kerosene oil lamp, and such a milk required only slight cooling to be safe for infants.

Rai KAILAS CHANDRA BOSE Bahadur, C.I.E., read a paper on the Milk-supply of Calcutta.

Dr. NEWELL, health officer of Lahore, read a paper on Some Practical Points in the Indian Milk Problem, in which he showed from his experience, supported by veterinary authorities, that generally speaking tuberculosis was uncommon in Indian cows. He insisted on the danger of cow-dung as a factor in the production of the disease, and recommended, among other things, training and certification of dairy workers and veterinary students, municipal free provision for dairies of trained dairymen, trained veterinary inspectors, the reduction of octroi charges and the award of prizes for clean milk, stringent licensing conditions in town dairies, provision of laboratories for milk analysis for large municipalities, and a provincial one for smaller ones, and the appointment of a milk commission.

A fourth paper, on the Milk-supply of Towns, by Major HARRISS, was sent in whilst the Congress was sitting.

Other Papers.

Among the other subjects dealt with were:—

Vital Statistics.—Papers were read on the Vital Statistics of Bengal, by Dr. C. A. BENTLEY, and by Babu BEPIN BEHARI BRAMACHARI on Mortality in the Cossipore-Chitpur Municipality. Education of the Public in Hygiene was discussed in a short paper by Major T. G. N. STOKES, I.M.S., and was the occasion of a detailed reply by Major W. GLEN LISTON, I.M.S., while Infantile Mortality, its Cause and Prevention, was dealt with by Rai KAILAS CHANDRA BOSE Bahadur, C.I.E. These two papers created some interest.

Inspection of Food and Drugs.—In an able paper Dr.

NAIR explained how little was or could be done in the cities of India to prevent adulteration of food and drugs — Dr **NEWELL** urged a general Act giving adequate powers to local governments to deal with local requirements, as well as a separate Pharmacy Act

Medical Inspection of School Children was the subject of a paper by Dr **AMRITARAJ**, and in the discussion which followed it was shown that in no province had this been systematically taken up

Rural Sanitation —This was discussed in two papers, those of the Hon Khan Bahadur **SAYAD MAHDI SHAH** and Mr **MOTA LAL GOSH**

Rural Water supplies —The Government of India having asked for information as to the arrangement in each province for the provision of protected wells in rural areas, the following are abstracts of some of the replies —

Madras —The chief sources are rivers, tanks, and wells In dry weather the people dig pot wells in the river bed These are factors in the spread of cholera Tanks are reserved for drinking and others for bathing, but though guarded by watchmen strangers do not discriminate between them In villages draw wells are in use, as far as possible step wells are being converted into draw wells

Bombay —In Gujarat and the Deccan wells and rivers supply the drinking water Many of the former have steps and disseminate cholera It is common to sink wells in the beds of nullahs which dry up as soon as the rains stop They are mere pits in loose soil In the Upper Sind the wells are often near stables, cowsheds, and manure heaps, Near the delta of the Indus it is useless to sink wells, as they become brackish There the people have to resort to the "dhands' or pools left by annual inundation These are often disgustingly dirty as the hot weather advances Buffaloes waddle in them and pariah dogs bathe in them, and side by side people take the liquid mud to drink

Bengal —Wells are suitable for water supply in the districts of Bankura, Burdwan, Berbhun, and Midnapur, the soil in parts of these districts being laterite In other parts tanks, khals, or rivers are the sources The water is brackish A Government committee is considering the best methods of improving the water supply

United Provinces —The somewhat lengthy reply shows that grants have been given for improving existing wells and sinking tube wells on certain conditions

Punjab —The provision of protected wells has been in the main left to private charity and large sums have been expended The provision of good wells has been one of the conditions and rewards to villages in the canal colonies and elsewhere, but these rewards have been discontinued Hand pumps are in use in some districts

Burma —In the great part of the Delta of the Irrawady river the water from shallow wells is brackish and unsuitable Subsoil water is near the surface and prevents well sinking, and deep wells have failed to give potable water

On the Delta and coasts rain water tanks are common A sufficient water supply can be got by storage in tanks where the rainfall is over 80 inches a year Shallow pit wells are also used Farther inwards wells are relied on The method of drawing water gives easy means of pollution In Burma there is no efficient means for dealing with rural sanitation The Burmese are extremely conservative and lazy, and no form of pump yet tried has lasted more than a few months

The Engineering Section

In the Engineering Section many interesting subjects were discussed Fly proof Latrines by Major H A **FORBES KNAPTON**, I M S, Models of Sanitary Work in Madras, by Mr J M **LACEY**, Dust Prevention, by Mr E P **RICHARDS**, and Sanitary Problems of Madras, by Mr W **HUTTON**, provided much material for discussion, while the Relationship between English and Indian Sanitary Engineering Practice, by Mr G B **WILLIAMS**, and a Note on Sanitation on India, by Mr C N **MANDY**, were well worth hearing

The Conference came to an end on Nov 20th, probably to meet again next year at Lucknow or Calcutta All were loud in their praise of the way the Conference had been organised and the hospitality of Madras

THE MALARIA CONFERENCE

The Malaria Conference began on Nov 18th and lasted three days

The President's Address

Sir **PARDEY LUKIS**, I M S, Director General of the Indian Medical Service, welcomed the delegates in an able address, pointing out the work that had already been done and how much still remained With regard to the journal *Paludism*, he said it had not received adequate support, and it was contemplated to substitute for it a journal of Indian research He justified the existence and explained the work of the mosquito surveys, discussed the various methods of mosquito reduction, urged a pure water supply, discussed the quinine prophylaxis at some length, and concluded that for local reasons in India quinine prophylaxis must be largely restricted to the destruction of the parasites in the blood of those who are suffering from malaria in either its acute or its chronic form, especially in the fever season He discussed the etiology of blackwater fever and the group of allied diseases, and reviewed our present knowledge of the other febrile diseases to be dealt with, and urged his hearers to be "up and doing" and not to wait until some French or German parasitologist came along and discovered the secrets of the many continued fevers which daily confronted the Indian medical profession

The Epidemiology of Malaria in Madras was ably dealt with by Captain J H **HORNE**, I M S, in Bengal by Dr **BENTLEY**, in the Central Provinces by Major **STOKES**, in Imperial Delhi by Captain E C **HODGSON**, I M S, and in the Jeypore Agency Estate by Major E L **PERRY**, I M S

The Action of Quinine and the Treatment of Blackwater Fever gave Major A C **MACGILCHRIST**, I M S, an opportunity for discussing the much debated point, and his paper created some difference of opinion

The Diagnosis of Latent Malaria was dealt with by Captain H W **ACTON**, I M S, while Major P N **O GORMAN LALOR**, I M S, described the studies of malaria in Italy during 1910 Anti malaria measures in Bombay and quinisation of school children in the United Provinces were described respectively by Dr J A **TURNER** and Major J D **GRAHAM**, I M S

Stegomyia operations were well described by Major **LISTON**, Bombay, Dr **MHASKAR**, Karachi, Major **MACGILCHRIST**, Calcutta Captain **HORNE** Madras, and Major **O GORMAN LALOR**, Rangoon

Kala-azar formed the subject of interesting papers by Lieutenant Colonel C **DONOVAN**, I M S, and Captain T C **MCCOMBIE YOUNG**, I M S, while Captain F P **MACKIE**, I M S, read an interesting paper on Protozoal Diseases, particularly those due to trypanosomes

The interest in the Malaria Conference was well sustained throughout three days, the papers provided ample material for discussion and were of great interest

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Annual Meeting of the Liverpool Royal Infirmary Increase in the Honorary Staff

THE annual meeting of the trustees was held in the board room of the hospital on Feb 5th, under the presidency of Mr Ralph Brocklebank The honorary treasurer, in reviewing the financial position, said that the year had been full of critical and anxious moments but, despite all fears, the lay and medical staffs had worked loyally together During the year there had been a large number of changes among those attached to the hospital and also in the means and work of administration Three members of the committee resigned and two died By the death of Dr A T H Waters in June last, who was honorary physician from 1870 to 1886, the honorary staff lost their senior consulting physician Mr E J M Phillips, dental surgeon since 1881, resigned his post, and the vacancy was filled by the election of Mr S Hallam Dr John M Hunt, the honorary laryngologist, retired after 20 years of diligent service On June 30th, 1911, Mr Brocklebank resigned the position of chairman, and early in 1912 Mr H Wade Deacon was elected to the vacant position The new out patient department, which had been in constant use for just over a year, had fully proved its usefulness, and had come up to expectations in its adaptability for dealing with its work to the advantage both of the patients and staff The theatre there had been most useful in dealing with 1103 minor operations, to the relief of the other theatres in the main building. About the middle of the year the X ray department was moved to its new quarters, which had been fitted up with the latest equipment, and the new conditions enabled the staff to deal with that important work most expeditiously. Owing to the extra nursing staff required for the out-patient department and casualty beds, together with the fact that the amount contributed from the hospital funds of the nursing institution for many years had not been sufficient for the cost of nurses required, it had been decided to increase the amount this year. The attention of the committee having been called to the large number of in-patients who came from a distance, it was decided to make a charge towards the cost of maintenance. That result had proved satisfactory. The committee was glad to be able to report that ward accommodation on a site belonging to the infirmary would shortly be provided for the treatment of tropical diseases, all necessary arrangements having been settled between the committee and the committee of the Liverpool School of Tropical Medicine. 3974 patients had been admitted to the wards and 369 cases were received in the casualty wards. The expenditure, owing to the high price of coal, the increased demands for more expensive drugs and dressings used in the work of the new out-patient department, together with the extra contribution to the nursing home, showed an increase of about £1000. Every year, owing to altered conditions, the expenditure continued to grow, with the result that the hospital debt increased at the rate of about £2000 a year. On Dec. 31st £7500 were due to the bank, and it was proposed to transfer £1500, being one-tenth of the maintenance fund, which would leave the debt at £6000. That was a state of affairs the public ought not to allow to continue. A vote of thanks to Mr. Brocklebank for his services as president and for his donation of 100 guineas was carried. The Earl of Derby was unanimously elected president for the ensuing year. The committee has decided to appoint an additional honorary assistant physician. This step was necessitated by the additional work in the new out-patient department.

The Lancashire County Council and Sanatoriums.

At the quarterly meeting of the county council held at Preston on Feb. 6th Mr. H. Wade Deacon (the chairman of the finance committee) reiterated a strong word of warning against any premature capital outlay for the provision of permanent buildings as sanatoriums. Looking at the decrease of tuberculosis, he advised that temporary provision should alone be made. The small-pox hospitals which were erected at great cost stood empty. The following medical men were appointed members of the Lancashire Insurance Committee: Mr. John Chadwick, Mr. Robert Sephton, Mr. Charles J. Trimble, C.M.G., Mr. John E. Dunn, and Dr. Manley M. Fitzpatrick.

Feb. 11th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

AT the annual meeting of the Court of Governors on Feb. 12th the chief item of interest to the medical profession was the election of Mr. H. Gilbert Barling to the Vice-Chancellorship. The death of the late Vice-Chancellor, Alderman Beale, was a great loss to the University, for he was a man with unusual powers, a wide experience of affairs, and a judicial mind, who had steered the University safely through its early difficulties. He was therefore a difficult man to follow. Mr. Barling has high qualifications for the post. He took an active part in the transformation of the old Mason College and the foundation of the University. As a teacher in several capacities, an active hospital surgeon, and a member of the University Council, he has served a long apprenticeship to the post, and will bring to it a trained scientific mind and academic knowledge as well as a knowledge of men and affairs. The report of the council mainly dealt with finance, but there are several interesting statements. The colliery owners of the South Midland district have presented £500 annually to be applied to the study and prevention of mine disasters. The money will be spent partly on a stipend for a lecturer and partly on travelling expenses to nine rescue stations and on apparatus. An important arrangement has been made with the Board of Agriculture for carrying on research bearing upon agricultural zoology, from which much is expected.

The Insurance Act.

There are in Birmingham about a quarter of a million insured persons, and by now the great majority have chosen their doctors. As in other places, they are very unevenly divided among the various practitioners. One practitioner has registered nearly 4000 and two others have more than 3000. Careful observations of the proportion the number of actual patients treated bears to the number of members enrolled have been made in certain quarters, and the experience of the first month has yielded a percentage of from 17 to 20. A local Pharmacopœia has been prepared containing 120 items, and the prescribing and dispensing appear to be working smoothly. At a mass meeting of chemists presided over by Mr. J. Radford, President of the Midland Pharmaceutical Association, an address was given by Mr. Nethercoat, who said that for the first time the Act gave official recognition to pharmacists, and that was going a long way towards the ideal for which they had been working during the 70 years' existence of the society. 93 per cent. of all pharmacists who were entitled to go on the panels had agreed to serve, and the remainder supported the principle on which the tariff was fixed. They had got State recognition of the registered chemist as the dispenser of medical prescriptions. He thought the change would improve the relations between the medical profession and the pharmacist.

Death of Sir Thomas Chavasse.

The death of Sir Thomas Chavasse, the senior surgeon to the Birmingham General Hospital, removes a very familiar figure from medical circles in the city. A man of high principles and distinguished attainments, his unexpected death will be deplored by a very large circle.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Watching the Dead.

"GWYLNÔS"—literally watch-night—a still surviving custom in some parts of Wales, has recently come in for a considerable amount of condemnation at the hands of those who are responsible for the health of the country. It has been said, quite justly, that for several persons to congregate in a small, probably very ill-ventilated, apartment in company with a dead body can hardly be wholesome, and speedy ill-results may follow when the body is that of one who has died of an infectious complaint. Efforts are accordingly being made to put an end to the custom, concerning the origin of which there is some difference of opinion. One view is that the object of the watching was to prevent the body being taken away by body-snatchers for the purpose of dissection in the medical schools. It appears probable, however, that the custom is much more ancient than the period of body-snatching, and is a survival of the practice once prevalent in Roman Catholic countries of carefully watching the bodies of the dead prior to burial. Whatever be its origin, in the interests of public health the custom should now be no longer permitted.

Cardiff Medical School.

The Cardiff Medical School since its establishment has been housed in the old infirmary buildings in Newport-road, and almost within a stone's throw of the present King Edward VII. Hospital. From time to time extensions have been made by erecting iron and wooden buildings, but it has long been recognised that the accommodation is altogether inadequate for the needs of the school. When designing the new University College buildings in Cathays Park the medical school was provided for, but as the college buildings are being put up piecemeal it was realised that it would be some time before the medical school could give up occupation of the present buildings. In order to put an end to the existing unsatisfactory conditions, and also with a view of providing special facilities for research work, Mr. W. J. Thomas, a colliery proprietor, in the Rhondda valleys, offered to the college authorities 10,000 guineas for the purpose of erecting suitable buildings on the Newport-road site, and he has recently increased this sum to £12,750. The objections to retaining the present site for a medical school are partly sentimental and partly practical. The college authorities are very anxious that the whole of the college buildings should be grouped together in Cathays Park, and, as Principal E. H. Griffiths has pointed out, a medical school in Newport-road would conflict with the ideal of the college as an entity which is so important a consideration in university life. From the practical point of view the upkeep of a separate establishment would involve additional expenditure of possibly £1000 annually. On the other hand, it is important that the medical school should not be too far from the hospital, and in this respect Cathays Park is at a considerable disadvantage compared with Newport-road. Sir Isambard Owen has advised very strongly that the offer of Mr. Thomas should be accepted and the Newport-road site utilised, and at the last meeting of the council of the college it was decided to follow his advice and to proceed with the erection of the new buildings.

Sanatorium Benefit in Wales.

The National Insurance Act provides that the Welsh Insurance Commissioners, and not the Local Government Board as is the case in England, shall control the distribution of all moneys available under the Act for the purpose of providing or making grants in aid of sanatoriums and other institutions. The Commissioners have sanctioned the arrangement which has been arrived at between the Welsh National Memorial and the county councils of Wales and Monmouthshire whereby the administration of the sanatorium benefits shall be in the hands of the memorial, the county councils agreeing to make contributions, if required, to the amount of a sum equal to a rate of ½*d.* in the £. With a view to arriving at some general agreement a conference was recently held at Llandrindod Wells between the Welsh Commissioners and representatives of the county councils, including the county medical officers of health, when Dr. H. Meredith Richards, the vice-chairman of the Commissioners, pointed out that many preventive measures, such as house-to-house inspection, supervision of food supplies, and general sanitary supervision, were incumbent on all local sanitary authorities irrespective of the presence or absence of tuberculosis, though these obligations became more insistent in the actual presence of the disease. One of the most important matters considered at the conference was the relation of the tuberculosis officers to the county medical officer of health, concerning which it is probable that some difficulties may arise, for with only one or two exceptions the county medical officers of health in the Principality were not at all anxious to have the administration of sanatorium benefits placed in the hands of the National Memorial, foreseeing that certain administrative difficulties were very likely to arise. The practical outcome of the conference was a decision to carry on the tuberculosis campaign on broad national lines and not in piecemeal fashion, county by county or borough by borough. Having this decision in mind, the Cardiff corporation has decided to work in coöperation with the National Memorial, although the health committee had previously advised that a separate organisation would best meet the needs of the town.

Medical Treatment of the Uninsured in Cardiff.

The medical practitioners of Cardiff have expressed their willingness to attend the uninsured members of friendly societies, except juveniles, at 8*s.* 6*d.* per member per annum, including the supply of medicines and the giving of certificates. The societies, however, have not agreed to these terms and are desirous of paying 6*s.* 6*d.* per annum for each uninsured member, including those over 65 years of age and permanent sick members, who are in receipt of an income not exceeding 45*s.* per week. They agreed to pay 8*s.* 6*d.* per annum for all new entrants irrespective of age and income, and for those receiving an income over 45*s.* per week, and suggested 4*s.* 4*d.* per annum for the juvenile members of the societies.

Feb. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

National Health Insurance in Edinburgh.

AT a meeting of the Local Insurance Committee held on Feb. 11th the applications of insured persons wishing to make their own arrangements under the Act were considered. It is understood that these were very numerous in the Edinburgh area. It was agreed to withhold permission of this sort from all except those falling under the following heads: (1) Insured persons at present ill and under the care of a non-panel practitioner; (2) insured persons in the employment of, or resident in the houses of, non-panel practitioners; and (3) insured persons undergoing homœopathic treatment at the hands of a non-panel practitioner of this class. Permission was also given to various medical institutions to make their own arrangements of this sort. This decision practically falls into line with that settled for the Lothians and surrounding counties by their respective committees.

Presentation Portrait of Sir William Turner.

On Feb. 14th Mr. A. J. Balfour, as Chancellor, accepted, on behalf of the University of Edinburgh, a portrait of Sir William Turner, subscribed for by students and friends in all parts of the world in appreciation of his sixty years' service successively as demonstrator, professor, and principal of the university. Sir Robert Finlay, M.P., made the presentation on behalf of the subscribers, and Mr. Balfour, in accepting custody, paid a high tribute to Sir William Turner, and touched upon the great academic change which had taken place contingent upon the successful effort to make the modern university keep pace with modern needs. The portrait, which is the work of Sir James Guthrie, P.R.S.A., is of three-quarter length, and is an admirable likeness in every way.

Edinburgh Royal Medical Society.

This society held its annual dinner on the evening of Feb. 11th, under the chairmanship of Dr. R. Murray Lyon, senior president, in the society's hall. Mr. W. Arbuthnot Lane, who earlier in the day had delivered a lecture under the auspices of the surgery department on "Intestinal Stasis," was the guest of the evening. There was a full attendance of Fellows and Members, and the speeches fell no whit short of the high level usually attained at this function.

Glasgow Slums and the Medical Faculty.

The treatment of consumption and the housing question in Glasgow formed the basis of a number of resolutions passed recently by the Royal Faculty of Physicians and Surgeons of Glasgow, and submitted by a deputation from that body before the corporation at a sederunt last week. The deputation was headed by the President, Dr. James A. Adams, who said they were present in no carping spirit, but rather to try to support the council in the efforts they were making to deal with very important health subjects. If slum properties were swept away their value would be returned a hundredfold to the community in better health. Professor J. Glaister submitted the first two of four resolutions. These were:—

1. That the Faculty have learned with satisfaction of the action already taken by the corporation of Glasgow in closing houses and tenements in the slums of Glasgow which are the breeding places of [illegible]

Speaking to the second resolution Professor Glaister said there were bound to be advanced cases of consumption living under conditions which were entirely inimical, and there was a section of the Public Health Act which stated that such persons without proper lodgings must be provided for by the municipality. They knew from medical experience that the disease was spreading through imperfect housing conditions, and his opinion was that in very advanced and incurable cases patients might have accommodation in which they could die in comfort. Dr. Ebenezer Duncan submitted the latter two of the four resolutions. These were:—

3. That in view of the rapidly accumulating experience regarding the disheartening results which follow the return of sanatorium

subject discussed. On this question opinion was sharply divided. Some speakers urged as essential to the making of good professors in medical science the possession of extensive theoretical knowledge. This view was ably championed by Professor Weiss and Dr. Lucas-Championnière. Other speakers, on the contrary, among whom was Professor Widal, held that in the professors of the future practical teaching and personal research should have pre-eminence over theoretical knowledge, and this opinion was largely supported. During the session the new statute concerning the matter was voted on. The principal reform effected is that whereas at present the test of admissibility to the "aggrégation" being essentially theoretical, the unfortunate successful candidates who fail to secure a post are compelled to continue to devote themselves to these theoretical studies, in future the admissibility will remain valid for nine years, so that a candidate who has once been declared eligible will be released from further theoretical tests, and will thus be able to continue his personal researches. The plan voted by the Superior Commission aims principally to favour specialisation among the new *agrégés*, in order that all branches of medical teaching shall henceforth be taught in the faculties and schools of medicine, which has not hitherto been the case. Finally, it was voted to obtain public powers for higher grants in favour of laboratories.

Feb. 17th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Public Health Statistics.

AT a recent meeting of the officers of public health in Vienna a preliminary report dealing with the health statistics for 1912 was read by Dr. Böhm, the President of the Board of Health The figures relating to the mortality show the remarkable and unexpected fact that during that year Vienna had the lowest death-rate amongst all the European capitals, the computed proportion being 14·06 per 1000. There died altogether 32,131 persons in 1912 as compared with 33,684 in 1911 (14·06 as compared with 15·68 per 1000), whilst ten years ago the corresponding ratio was 17 89 per 1000. In this reduction of the death-rate the various fatal diseases participate in an unequal degree, all diseases incidental to infancy and childhood having become less frequent, whilst those incidental to middle life, and especially to old age, have increased markedly. This is illustrated by the fact that ten years ago there died 8880 children under one year of age and 7281 persons older than 60 years, whereas in 1912 there died 5922 children under one year of age and 9568 persons over 60 years Of the latter category 1434 were over 80 years, as compared with 1180 in the year 1903. This shows a direct reversal of the conditions. As regards the causes of death, the following figures are interesting. Tuberculosis last year claimed 6298 victims, as compared with 7748 during the similar period ten years ago. For the same two periods other diseases of the respiratory tract caused 4174 deaths, as compared with 5290, and diseases of the alimentary tract caused 2911 cases, as compared with 3865; an increase was noted, however, in fatal diseases of the circulatory system—namely, 4835 as compared with 3302, and in deaths from malignant affections 2753, as compared with 2157. The facts may be summarised in the remark that accidental preventable diseases have gone down in numbers, whilst diseases due to exhaustion of vital force (arterio-sclerosis, degeneration of the myocardium, and cancer) have increased. A consideration of the figures leads to the welcome conclusion that the average duration of life of the deceased persons was much higher than previously, but it also shows that the decrease of births is as well marked in Vienna as in all other civilised countries of Europe In Vienna only 40 503 living children were born last year, against 45,830 in 1903 and 50,327 in 1893 Thus at least 100,000 living children were born less in the last decade than in the previous one. A continuation of this decline must inevitably result in the number of the population becoming stationary or even diminishing. The hygienic measures which have improved the bulk of the population have considerably narrowed the field of activity of the general practitioner, but on the other hand this loss of income is more than counterbalanced by the new openings for medical work created in connexion with the prevention of disease both in the homes of the people and in industrial establishments, the care of infants, and the protection of children.

Professor Chiari's Birthday.

The well-known rhino-laryngologist, Professor Otto Chiari, recently celebrated the anniversary of his sixtieth birthday, and on this occasion he was the recipient of many compliments and congratulations. His pupils published a Festschrift, containing a number of interesting articles by the most prominent of his previous assistants. He was also entertained at a banquet which was attended by representatives of many foreign nationalities, including English and American societies, and the Vienna Laryngological Society held a special meeting for the purpose of doing honour to its president.

Students' Protest against Recent Modifications in the Medical Curriculum.

Some time ago a new order of studies was established at the University of Vienna, its effect as regards the medical classes being that, after having worked for three semesters (or half-year terms) at the University, the student has to pass four preliminary *viva voce* examinations on biology and a practical examination on anatomy within 12 weeks, whereas previously to the new order coming into force these could be passed in the course of the fourth and fifth semester. Students who do not pass them within the 12 weeks will not be allowed to proceed to clinical study in the wards. These regulations are open to the objection that they might possibly deprive a student of one semester and cause him to lose any scholarships which he might possess. The medical students have therefore taken action of the nature of a protest against them, sending petitions to the dean of the Medical Faculty and to the rector, asking for either a lenient application of the new regulations or the restoration of those which they have superseded.

Feb. 17th.

REMEDIABLE DEFECTS IN CHILDREN OF SCHOOL AGE.—The mid-session address before the Nottingham Medico-Chirurgical Society was delivered on Feb. 5th by Dr. Mary Thorne, who took the Remedial Defects in Children of School Age as her subject. She said that medical inspection had been carried on in schools now for ten years; this had taught us that healthy bodies and healthy minds can only come from healthy parents and healthy surroundings. More attention should be paid to the daily functions of the body, and in order to secure this there should be sufficient and decent lavatory accommodation in every school, and children should be allowed to leave the class if necessary. If these functions are neglected constipation inevitably arises, followed by anæmia, indigestion, and dysmenorrhœa. Fortunately, there is a steady improvement in the lavatory accommodation. All girls should have plenty of active movement in the open air, but not in competitive games; the latter are a mistake for girls of 13 to 16 years. Curiously enough, town children have better playgrounds than village children. The lecturer then briefly dealt with posture curves, flat feet, desk accommodation, and the position of the windows in the classroom. The light should always come over the left shoulder. The teeth were too often neglected, and all second dentition teeth should be stopped on the first sign of decay. The children should clean their teeth at least every night. The importance of clean heads was being instilled into the parents, because they found the children were refused by the factory surgeons if their heads were verminous. A very large number of blind and deaf children owed their afflictions directly to the sins of their parents. Heredity was also the largest factor in the causation of mental deficiency. Thus it became the duty of doctors to impress upon parents, teachers, clergy, and others, the great importance from a medical point of view of encouraging a moral life. Finally, the lecturer deplored the present system of class teaching as opposed to individual teaching; 5 per cent. of the children leave school without being able to read and write sufficiently well to be of any practical use. There should be a simpler code of instruction; little should be taught, but that little should be well taught.

Obituary.

MALCOLM MACDONALD McHARDY, F.R.C.S. EDIN., M.R.C.S. ENG.,

LATE PROFESSOR OF OPHTHALMOLOGY AT KING'S COLLEGE, LONDON, SENIOR OPHTHALMIC SURGEON TO KING'S COLLEGE HOSPITAL, AND CONSULTING SURGEON TO THE ROYAL EYE HOSPITAL.

Malcolm Macdonald McHardy, for many years professor of ophthalmology in, and surgeon to, King's College Hospital, London, was the sixth son of Admiral J. B. B. McHardy by Horatia, daughter of Admiral Pascoe, and grandson of Nelson's famous flag-lieutenant. He was born at Springfield, near Chelmsford, Essex, on March 15th, 1852, and received his early education at the Royal Naval School, which was formerly at New Cross, and afterwards removed to Eltham in Kent. He early showed that he inherited his father's magnificent energy and physique and passionate love of the sea, and he often used to say that but for his mother he would have gone into the Navy, whilst his father wished him to be an engineer. At the age of 17 he was entered at St. George's Hospital as a medical student, and from that time forward entirely supported himself by working as an assistant to private doctors by night and studying as much as he could by day, he being so self-reliant that he entirely refused help from his father, who had others more needy of aid and far less capable of fighting their way in the world than he. He qualified as M.R.C.S. Eng. in 1873 and F.R.C.S. Edin. in 1877, and was assistant house surgeon at Leicester Infirmary, ophthalmic assistant and ophthalmic registrar to St. George's Hospital, London, surgical registrar to Charing Cross Hospital, house surgeon to the Belgrave Hospital for Children. He went for one or two voyages in the old sailing ship *Kong Sverre*, and in 1878 became honorary surgeon to the Royal Eye Hospital, Southwark, which institution he was the chief means of rebuilding and bringing up to its present high state of efficiency, and in 1880 he was elected professor of ophthalmic surgery to King's College He edited the fourth edition of "Wells on Diseases of the Eye," with an original ophthalmoscopic atlas; and contributed several practical papers on general surgical subjects to St. George's Hospital Reports before he exclusively devoted his attention to ophthalmology.

Amon
"On
Tuber

Cataract," and "On the Operative Treatment of Immature Senile Cataract and its Artificial Ripening by Trituration." But his chief accomplishment was the invention in 1882 of the self-registering perimeter, an account of which was published in the *Ophthalmic Review* for that year. This was a genuine boon to the profession, and was met with universal approval all the world over. The invention of this instrument brought him not only fame, but many friends, especially from Germany and America. It is a remarkable testimony to the thoroughness of McHardy's perimeter that in an age when mechanical science has been so progressive, yet for the last 30 years no improvement has been made in it, nor has it been superseded. But all who ever saw McHardy operate or demonstrate cases were always struck with his essentially practical nature and the mechanical bent of his mind. He was an extremely dexterous operator upon the eyeball. His incisions were precise, beautifully even and neat, and so gently made that little, if any, reaction followed, except in the most diseased eyeballs. He had hands as steady as it is possible to imagine, and his operations in the most difficult cases of glaucoma, when the anterior chamber was practically abolished, were most beautiful to watch. He was always an advocate of operation in primary simple glaucoma, and generally endeavoured to obtain a cystoid cicatrix at one angle of the wound by drawing up a strand of iris tissue free from pigment, beneath the conjunctival flap. This he was doing in the early nineties with considerable success.

McHardy was a man of striking physique, being a first-class heavy-weight boxer and a good all-round athlete; but his commanding and domineering personalities brought him as many enemies as his good qualities brought him friends. All admired his honesty and ability, but his forcible nature and unconventional language made many dislike him. With hospital work he was particularly in his element, and his devotion to duty may be testified to by the fact that he would be seeing patients from 3 in the afternoon till 8 and 9 at night, and his notes were always very precise and accurate. His out-patients loved him and would wait hours to see him; while he, being a most versatile man, knew something of most of their trades and occupations, which, coupled with his breezy, genial nature, and thorough examination of their case, endeared him to them all. McHardy died at Dumfries, N.B., on Feb. 8th, aged 60.

The funeral took place at Dumfries. The staff of King's College Hospital was represented by Mr. L. V. Cargill, the senior ophthalmic surgeon; whilst the council of

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians of London held on Jan. 30th, and of the Council of the Royal College of Surgeons of England held on Feb. 13th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 98 candidates (including two ladies—Miss Merlin Kingsley, Calcutta and Manchester Universities, and Miss Minerva Ellen Reid, M.B. Toronto, Toronto University), who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board, and have complied with the necessary by-laws. The following are the names and schools of the successful candidates:—

Kenneth Blackie Aikman, B.A. Cantab., Cambridge University and University College Hospital; Charles Harry Powell Allen, Madras University and University College Hospital; George Stanley Applegate, Bristol University; Christian Victor Aserappa, D.P.H. Oxon., D.T.M. & H. Cantab., L.M.S. Ceylon, Ceylon Medical College and London Hospital; Stephen Grange Askey, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Mark Avent, B.A. [illegible] University College Hospital; [illegible] John Henry Bennett, King's [illegible] Paul Theodore Gustave Bergouignan, M D. Paris, Paris University; Alured Charles Lowther O'Shee Bilderbeck, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Walter Folliot Blandford, B.A. Cantab., Cambridge University and St. George's Hospital; Maurice Frederick Bliss, London Hospital; Ellis Campbell Bowden, London Hospital; Edward John Yelverton Brash, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Robert Traill Brotchie, London Hospital; Herbert Horan Brown, B.A. Cantab., Cambridge and Leeds Universities; Stacey Archer Burn, St. Bartholomew's Hospital; Anthony Clifford Clifford, B.A. Cantab., Cambridge University and Guy's Hospital; Albert George William Compton, Cambridge University and St. Mary's Hospital; William James Cran, M.B., Ch.B. New Zealand, Otago University and St. Bartholomew's Hospital; William Henry D[illegible]-Smith, University College Hospital; Alfred Beuthin Danby, Guy's Hospital; Francis L[illegible] Daunt, St. Thomas's Hospital; Kenneth Bruce Dickson, B.A. Cantab., Cambridge University and St. George's Hospital; Philip Geoffrey Doyne, B.A. Oxon., Oxford University and St. Thomas's Hospital; George Dunluce Eccles, Guy's Hospital; Eric Alfred Charles Fazan, Middlesex Hospital; Edwin James Foster, M.B. Toronto, Toronto University and London Hospital; Ivor Stanley Gabe, Durham University and London Hospital; Norman Garrard, B.A. Cantab., Cambridge University and Guy's Hospital; Gerald William Blackman Garrett, B.A. Cantab., Cambridge University and Guy's Hospital; Harold Cane Godding, Guy's Hospital; Edgar Mervyn Grace. B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Bernard Grellier, L.D.S. Eng., Charing Cross Hospital; Cyril James Anthony Griffin, University College Hospital; Frank Arnold Gunesekera, L.M. & S. Ceylon, Ceylon Medical College and London Hospital; Alfred Ernest Hallinan, Charing Cross Hospital; William Edward Hallinan, Charing Cross Hospital; Sydney Hartley Hay, M.B., Ch.B., New Zealand, Otago University and Middlesex Hospital; Arthur Martin Henry, L.D.S. Eng., Guy's Hospital; Frederick Malcolm Sterling Hulke, Middlesex Hospital; Frank Cornwell Hunot, Guy's Hospital; Theodor Julius Juta Jeppe, Cambridge University and St. Thomas's Hospital; David William John, B.A. Cantab., Cambridge University and Guy's Hospital; Robert Edmund Johnston, B.A., M.B. Toronto, Toronto University and Middlesex Hospital; Manishanker Khushaldas Joshi, L.M. & S. Bombay, Bombay University and London Hospital; William Henry Kauntze, B.A., M.B., Ch.B. Manchester, M.B., B.S. London, Manchester University; Kenneth John Taylor Keer, Guy's Hospital; Francis Harry Kelly. Middlesex Hospital; Merlin Kingsley, Calcutta and Manchester Universities and Royal Free Hospital; Herbert Arnold Lake, M.R.C.V.S., University College Hospital; Harold William Latham, London Hospital; Hubert Vere Leigh. Guy's Hospital; Frank Graham Lescher, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Alfred Robinson MacMullen, B.A. Cantab., Cambridge University and London Hospital; Kamberranda Cariapa Mandana, Madras [illegible]x Hospital; Henry Hugh Mathias, B.A. [illegible]versity and London Hospital; Arthur [illegible]ondon Hospital; Louis Marie Jacques [illegible] Cyril Cassan Messiter, L.M.S.S.A., M.A. [illegible]versity and St. Bartholomew's Hospital; [illegible] Moore, Guy's Hospital; Oswald Gayer Morgan, B.A. Cantab., Guy's Hospital; Donald Ewart Morley, London Hospital; Lionel Page, Bristol University; John Lansdowne Perceval, Guy's Hospital; Oswald Pitt, Manchester University; Courtenay Henry Gerard Pochin, Guy's Hospital; Lao Htin Poh, Calcutta University and Middlesex Hospital; Herbert [illegible], Oxford University and St. George's Hospital; [illegible], M.B., B.S. Lond., M.B., Ch.B. Manchester, [illegible]; Stanley Owen Rashbrook, London Hospital; [illegible], St. Thomas's Hospital; Minerva Ellen Reid, M.B. Toronto, Toronto University and Royal Free Hospital; Pierre Roux, London Hospital; John Alfred Ryle, Guy's Hospital; William Henry Price Saunders, Middlesex Hospital; Bernard Edward Patrick Sayers, Middlesex Hospital; William Simpson, St. Bartholomew's Hospital; Reginald Westmore Spence, Westminster Hospital; Charles Marshall Stallard, Manchester University; Rex Stansfeld, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Humphrey Meigh Stephenson, Cambridge University and London Hospital; William John Francis Symons, B.A. Cantab., Cambridge University and St. Thomas's Hospital; James Robert Karran Thomson, London Hospital; Maurice Lawrence Treston, London Hospital; Henry de Paiva Buchanan Veale, J.P., L.S.A., Leeds University; Aubrey William Venables, St. Mary's Hospital; Alfred Stewart Wakely, King's College Hospital; Horace Frederick William Ward[illegible] University and St. George's Hospital; [illegible] B.A. Cantab., Cambridge University [illegible] Philip James Watkin, Guy's Hospital [illegible] B.A. Ca[illegible] pital; [illegible] Wicker[illegible] pital; Bernard Woodhou[illegible] Wilson Woods, London H[illegible] Hospital.

Diplomas in Public Health were also conjointly conferred upon the following 12 candidates—viz:—

Frederick John Ayre, L.R.C.P., M.R.C.S., L.S.A., St. Mary's Hospital and University College, Cardiff; Harold Balme, F.R.C.S., L.R.C.P.. M.R.C.S., King's College; Jamasp Oursetji Bharucha (Lieutenant, I.M.S.), L.R.C.P., M.R.C.S., L.M. & S. Bombay, Bombay University and King's College; Elsie Mary Chubb, M.D., B.S. Lond., Royal Free Hospital and University College; William Edmund Cooke, M.B., Ch.B. Liverp., Liverpool University; Archibald Ferguson, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Clifford Allchin Gill (Captain, I.M.S.), L.R.C.P., M.R.C.S., University College; Harvey Hilliard, L.R.C.P., M.R.C.S., St. George's Hospital and University College; John Edward Hodgson (Major, R.A.M.C.), L.R.C.P., M.R.C.S., Manchester University and Royal Army Medical College; Herbert Michael Henry Melhuish (Captain, I.M.S.), L.R.C.P., M.R.C.S., St. Bartholomew's Hospital and University College; Alexander Loftus Otway (Captain, R.A.M.C.), M.B., B.Ch., B.A.O. Dub., Dublin University and Royal Army Medical College; and Percy Rose, L.R.C.P., Guy's Hospital and University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The undermentioned diplomas were also conferred by the Council on the following:—

F.R.C.S.—Bernard Constable Maybury, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Thomas's Hospital.

L.D.S.—Lawrance Richards Hr[illegible] Hospitals; William Douglas [illegible] Hospitals; Oscar Henry Tit[illegible] Hospitals; Robert Douglas I[illegible]

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. K. Bötticher, extraordinary professor of surgery, has been appointed Director of the surgical side of the Lichtenberg Hospital; Dr. Friedrich Gudzent has been recognised as *privat-docent* of Medicine; Dr. Ludwig F. Meyer and Dr. Joh. Eckert as *privat-docenten* of Children's Diseases; and Dr. A. Grotjahn as *privat-docent* of Social Hygiene.—*Breslau:* Dr. Josef Forschbach, *privat-docent* of medicine, has been granted the title of Professor.—*Brunswick:* Dr. Adolf Bingel, senior physician of the Ducal Hospital, has been granted the title of Professor.—*Halle:* Dr. E. Abderhalden, professor of physiology, has been awarded the Helmholtz Prize of the Berlin Academy of Sciences. The value is 1800 marks (£90).—*Leipsic:* Dr. Franz Hofmann, who has held the chair of Hygiene for 35 years, intends to retire at the age of 70, which he will reach in the summer.—*Naples:* Dr. U. Masucci has been recognised as *privat-docent* of Medical Semeiology.—*Pavia:* Dr. Giovanni Perez, extraordinary professor of surgical pathology, has been promoted to Ordinary Professor.—*Pisa:* Dr. Alfonso Sertoli has been recognised as *privat-docent* of External Pathology.—*Rome:* Dr. Vincenzo Caraffa has been recognised as *privat-docent* of Medical Pathology.—*Saratoff:* Dr. I. N. Bystrênin, of Kazan, has been appointed Professor of Pædiatry.—*Sienna:* Dr. Onofrio Fragnito, extraordinary professor of neurology and psychiatry, has been promoted to Ordinary Professor.—*Strasburg:* Dr. A. Hamm has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Turin:* Dr. Francesco Lasagna has been recognised as *privat-docent* of Otology and Laryngology.—*Vienna:* Dr. Richard Buer has been recognised as *privat-docent* of Medicine.—*Würzburg:* Dr. Ernst Schmidt has been recognised as *privat-docent* of Surgery.

MIDDLESEX HOSPITAL.—Arrangements are being made for the production during the season of a new musical play, entitled *Claude Abroad*, by Charles and Muriel Scott Gatty, with music by Sir Alfred Scott Gatty and Charles Scott Gatty, for the benefit of the Middlesex Hospital. Lady Churston (Miss Denise Orme) will return to the stage for these performances, and will be supported by many well-known amateurs.

THE SECOND INTERNATIONAL "FIRST AID" CONGRESS.—This congress is to be held at Vienna in September next. Of the British sectional committee the Earl of Londesborough has accepted the presidency, and the vice-presidency has been accepted by Lord Claud J. Hamilton, M.P., while a very influential and thoroughly representative committee have accepted office. Any application or inquiry concerning the same may be addressed to Mr. Samuel Osborn, Constitutional Club, Northumberland-avenue, W.C.

Sir Richard Douglas Powell will deliver two Emeritus lectures on Fridays, March 7th and 14th, at 3 P.M., in the Middlesex Hospital Medical School, on the Climatic Treatment of Pulmonary Diseases.

MEMORIAL TO SIR WILLIAM ALLCHIN.—In memory of the late Sir William Allchin, consulting physician to Westminster Hospital and physician extraordinary to H M. George V., who died on Feb. 8th, 1912, a brass tablet has been placed in the hospital chapel, and a replica of his portrait, painted by Sir Luke Fildes, R A., and presented by Lady Allchin, has been hung in the board-room, where it is thought many of his friends and former pupils would be glad of the opportunity of viewing it.

MEMORIAL TO A MIDLOTHIAN PRACTITIONER.—On Feb 8th, in Lasswade Churchyard, in the presence of representatives of the various public bodies of the district and of the public, a memorial to the late Dr. C. J Allan, of Lasswade, was unveiled by Provost Gilchrist. It is in the form of a handsome Celtic cross in granite, the cost of which has been subscribed by the inhabitants of the district. The Rev. R. M. Hardie, parish minister of Cockpen, who presided over the ceremony, made reference to Dr. Allan's valued work for nearly half a century, both in his profession and as a member of the various boards and institutions.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Administration of the Insurance Act.

THE administration of the Insurance Act has occupied much of the attention of the House of Commons since the beginning of the year This has been mainly evident at question time, when scarcely a day has passed without the appearance on the notice paper of a large number of questions dealing with various matters, sometimes of principle, sometimes of detail, which have arisen from time to time. Amongst members who have particularly taken an interest in questions arising out of medical benefit are Sir PHILIP MAGNUS, Sir HENRY CRAIK, Mr. WORTHINGTON EVANS, Mr. GODFREY LOCKER LAMPSON, and Mr. CASSEL. The former two have in a peculiar sense had a responsibility in the matter, as they represent university constituencies in which medical men are a very considerable element in the electorate. Mr. WORTHINGTON EVANS and Mr CASSEL have shown marked skill in mastering the administrative details of the Act and the Regulations The task of replying on behalf of the Government and the Insurance Commissioners has mainly fallen on the shoulders of Mr. MASTERMAN, the Secretary to the Treasury, whose Parliamentary ability in handling difficult questions has been recognised in all quarters of the House.

Limited Panel Service.

Many of the aspects of medical benefit were dealt with in the debate on the supplementary medical grant in aid on Friday, Feb. 7th. On that occasion the Chancellor of the Exchequer made a defence of the Government's policy. However, the discussions on the Appropriation Bill permitted the House of Commons to review it again. The point of interest in these discussions was the declaration of the Government in regard to the free choice of medical men and limited panel service.

On Wednesday, Feb. 12th, Mr MASTERMAN, in the course of a speech in which he again stated that professional medical secrecy was safeguarded under the system of records which panel practitioners were required to keep, went on to say that the Government always had intended, and still intended, that the Insurance Committees, if they wished to do so, when they had assured adequate medical attendance for all insured persons within their areas, should permit under certain conditions arrangements in connexion with doctors who might not be on the panel. For example, he believed that the London Insurance Committee had granted or was granting a general exemption under Section 15 (3) allowing nurses at hospitals to make their own arrangements with doctors at the hospitals who were not, and who did not want to be, on the panel and who did not want to attend insured persons outside the hospitals Similarly conditions might be laid down with regard to allowing doctors to go on the panel to attend only a limited number of persons. This practice in the working of any Insurance Committee must be qualified by one dominant consideration—the duty of the Insurance Committee in conjunction with the doctors on the panel to see that every insured person within their area received adequate medical attendance. A medical man who did not want to have 1000 or 2000 insured patients, might be quite willing to go on attending at the ordinary insurance rate—say the servants in the houses where he had been attending. He had been in consultation with the Chairman of the London Insurance Committee on the subject, and he said, as the Commissioners said in conjunction with the Insurance Committee, that there was no kind of objection to these cases being met by Insurance Committees permitting doctors to go on the panel in order to attend a limited number of cases, so long as that was done in conjunction with an agreement with the doctors on the panel, and so long as the system could be interwoven with a system whereby adequate medical attendance could be given to every insured person within the area. He had not the slightest doubt that this could be done. The right honourable gentleman went on to refer to "a definite, deliberate and avowed attempt to break the Act to pieces in London." He maintained that the Insurance Committees when confronted with this avowed and organised conspiracy were perfectly justified in saying, "Until we have assured medical attendance for all the insured persons in our areas, if possible by the panel system, if not by some other system, we will not have the Act broken up by 'own arrangements'" The great bulk of requests for "own arrangements" which had come in to the Insurance Committees with which he had been in contact had not been *bonâ fide* applications at all. They had come in on forms all in the same handwriting, evidently the result of a canvass in which probably complete misapprehension had been created in the minds of insured persons as to the real meaning of the Act On the other hand, peace being restored, as he believed it was, the doctors, he anticipated, if only they were left alone would be found working the Act with ever increasing enthusiasm. With friendly conjunction between the Insurance Committees and the panel doctors, arrangements being made to meet the needs of all the insured persons in the area he saw no reason at all why in certain special cases the use of Section 15 (3) should not be allowed where special circumstances were made out for it What would be better still would be that doctors should, with friendly arrangements with their colleagues, come on the panel for a limited number of insured persons only.

Two Important Reservations.

Mr. MASTERMAN elaborated in some respects his statement on the use of Section 15 (3) in the debate on the third reading of the Appropriation Bill on Friday, Feb. 14th. He said that in regard to exceptional cases in which for some special reason doctors did not wish to enter their names on the panel for general work, and insured persons wished to choose those doctors, no obstacle would be placed in the way of Insurance Committees exercising their discretion in any manner which they desired in order to allow exceptional cases to be dealt with under the exceptional clauses of the Act so long as the Insurance Committees were fulfilling the primary purpose for which they were created—namely, to give medical benefit to every insured person within the Act. The Government agreed with the suggestion of the chairman of the London Insurance Committee that doctors who wished to take only a limited number of patients should be permitted to come on the panel for such limited number. But that was subject to two important reservations. The first was that it would be unfair that they should be allowed to pick out special lives with less than the average rate of sickness and yet receive the remuneration which the Government believed to be a liberal one for average lives. Doctors who took selected lives should be willing to receive less remuneration for those selected lives, in order that more remuneration might be given to those doctors who did not limit themselves to selected lives. The second condition must be that the Insurance Committees could only give consent to doctors taking a limited number of lives in conjunction with the free approval of medical men who took the general risk. The right honourable gentleman then went on to explain that there was no intention whatever of bringing in inspectors to examine the methods of treatment and diagnosis adopted by medical practitioners on the panel. On the question of mileage in difficult districts in the Lowlands of Scotland the Government were providing a special grant. The Commissioners would draw up a scheme of distribution, and it would be retrospective, so that the allowances would be paid from the commencement of the Act.

Tuberculosis Prevention (Ireland) Bill.

When the Tuberculosis Prevention (Ireland) Bill reached the House of Lords from the House of Commons on Thursday, Feb 13th, two of the clauses which originally stood in it had been struck out. The first two clauses were deemed important, but the Chief Secretary to the Lord Lieutenant for Ireland, Mr. BIRRELL, found that they were likely to produce opposition in the House of Commons. In order to allow the Bill to proceed as an uncontroversial measure he agreed to drop them.

The first clause which was struck out in Committee of the House of Commons extended the provisions of Part I of the Tuberculosis Prevention (Ireland) Act to the whole of Ireland.

Clause 2, which also disappeared, provided that certificates with regard to a person suffering from tuberculosis which had now to be sent to the medical officer of health should be sent to the medical superintendent of the nearest dispensary. The latter was to report to the sanitary authority.

The Bill has been read a third time by the House of Lords.

Royal London Ophthalmic Hospital, City-road, E.C.—Lang Clinical Research Scholarship. Salary at rate of £120 per annum. Also Senior House Surgeon. Salary at rate of £100 per annum, with board and residence.

Royal Naval Medical Service.—[illegible]

Royal Westminster Ophthalmi[illegible] West Strand, W.C.—Pathologist [illegible]

St. George's Dispensary and School Clinic, Surrey-row, Blackfriars, S.E.—Junior Medical Officer for three or six months. Salary at rate of £100 per annum. Also Surgeon to the Nose, Throat, and Ear Clinic for the Treatment of Elementary School Children. Salary at rate of £50 per annum.

Scarborough Hospital and Dispensary.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and allowance for laundry.

Sheffield Union Hospital, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments and rations.

Smethwick, Cornwall Works Dispensary.—Assistant Medical Officer. Salary £300 per annum.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

Southampton, Royal South Hants and Southampton Hospital.—Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board, and washing.

South Africa Lunatic and Leper Asylum Service.—Junior Medical Officer, unmarried. Salary £280 per annum, with quarters.

Stafford, Coton Hill Mental Hospital.—Assistant Medical Officer, unmarried. Salary £170 per annum, with residence, board, and laundry.

Stockport Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

Stockport Union, Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary £150 per annum, with apartments, rations, &c.

Stroud General Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Sunderland Children's Hospital.—Resident Medical Officer for six months. Salary £80 per annum, with board, residence, and laundry.

Swinton and Pendlebury Urban District.—Medical Officer of Health and Schools Medical Officer. Salary £325 per annum.

Ventnor, Royal National Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, &c.

Victoria Hospital for Children.—Surgeon to Out-patients.

Walsall and District Hospital.—Assistant House Surgeon. Salary £90 per annum, with board, residence, and laundry.

Western General Dispensary, Marylebone-road, N.W.—Honorary Physician.

Western Ophthalmic [illegible] N.W.—Non-resident House Surgeo[illegible] per annum.

West London Hospital, [illegible] House Physicians and Three House Surgeons for six months. Board, lodging, and laundry provided.

York Dispensary.—Resident Medical Officer, unmarried. Salary £140 per annum, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Castletown, Berehaven, in the county of Cork; and at Hoylake, in the county of Chester.

The Secretary of State for the Home Department gives notice of a vacancy for an Ophthalmic Specialist Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuits Nos. 21, 22, and 36.

Births, Marriages, and Deaths.

BIRTHS.

Dyson.—On Feb. 12th, at Lower-road, Rotherhithe, S.E., the wife of Malcolm Goodworth Dyson, F.R.C.S., of a daughter.

Jordan.—On Feb. 19th, at 11, Bentinck-street, W., to Dr. and Mrs. Alfred C. Jordan, a son.

Pennington.—On Feb. 12th, at Queen-street, Mayfair, W., the wife of Drury Pennington, M.B., of a son.

MARRIAGES.

Adams—Appleyard.—On Feb. 15th, at St. Marylebone Parish Church, James Wilmot Adams, M.B., B.C. Cantab., to Irene, youngest daughter of the late Dr. James Appleyard, of Longford, Tasmania.

DEATHS.

Boyd.—On Feb. 15th, at Sloane Court, S.W., Campbell Boyd, L.R.C.P.I., L.M., the beloved husband of Isabell Boyd, after a short illness.

Chavasse.—On Feb. 17th, at The Linthurst Hill, Barnt Green, Worcestershire, Sir Thomas Chavasse, F.R.C.S., aged 58.

Dyson.—On Feb. 12th, at Lower-road, Rotherhithe, S.E., Malcolm Goodworth Dyson, F.R.C.S., aged 45 years.

Hart.—On Feb. 10th, at St. Stephen's-avenue, Ealing, Herbert Wheatley Hart, M.D., in his 55th year.

Scarth.—On Feb. 17th, at Stanghow, Isaac Scarth, M.B., B.S. Lond., B.Sc. Manch. Univ., the beloved husband of Rosa Marion Scarth, in his 59th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CHANGE OF ADDRESS.

When a medical man moves house it is only natural that he should wish to announce the fact to his colleagues as soon as possible, since early notice of the new address may save much inconvenience to himself and them. But at present the opportunities for making such announcements are limited. Professional etiquette rightly debars medical men from advertising their change of address in the lay newspapers, while the various directories—medical, Post Office, and telephone—appear at too long intervals to be of help during the period of worst confusion. It is thus not very easy for medical men to keep themselves and each other informed of removals within the profession, for the Post Office is a laborious medium of communication, and the students' gazette of any individual hospital reaches only one section of the medical world. This disadvantage has several times been brought to our notice by readers, and the remedy always suggested to us is that The Lancet should reserve a special place week by week for brief announcements of new addresses and new telephone numbers. After inquiry we have come to the conclusion that this form of publicity would be welcomed by our readers generally, and we therefore propose to institute a Change of Address column to come immediately after the announcements of Appointments and Vacancies.

VITAL STATISTICS OF BARBADOS.

A report on the Blue-book of Barbados for the year 1911-12 gives the population of the colony as 173,422—71,544 males and 101,878 females. The birth rate per 1000 was 35·2 and the death-rate 26·3. Illegitimate births numbered 3546, or 58 per cent. of the total births. The burials of children under a year old numbered 1605, giving a rate of 263 per 1000 births. The relation of infantile mortality to illegitimacy cannot be ascertained from the returns at present authorised by law; but steps for the reduction of the rate of infantile mortality are engaging the serious attention of the Government and the parochial authorities. The Barbados General Hospital, situated in Bridgetown, is maintained by Government grant, but is not directly under Government control. It is governed by a court of directors of 18, of whom 16 are so either *ex officio* or by appointment from the Legislature, and the remaining two are life members. In 1911 there were 3759 admissions, 276 deaths, and 27,132 out-patients. The daily average in hospital was 200. At the lazaretto there were 14 admissions and 12 deaths, leaving 116 inmates at the end of the year. The average daily number was 114·6. There is no legally compulsory segregation of lepers. The average maximum temperature was 83·8° F. and the average minimum 75·3°. The highest temperature for the year was 89·1° on August 10th, and the lowest 61·0° on Feb. 20th. The rainfall of the island for the year, as registered at 154 stations, was 59·28 in., which was rather below the average. The number of tourists visiting the island during the year was 2164. The visitors may be divided into three categories: (*a*) Those brought by tourist ships, who stay only for a day; (*b*) tourists from Europe and North America, who stay at the principal hotels or rent houses during the winter months; (*c*) visitors from South America, particularly Brazil, who rent houses near the sea during their stay, which, owing to the island's reputation as a health resort, is generally of considerable duration. For the special accommodation of this class, Brazilian hotels are now being established. In connexion with one of the principal articles of manufacture in the colony—rum, to wit—it is remarked in the report that "a by-product of the manufacture is fusel oil. The quantity is not large enough for profitable export, but every drop is much sought after as a lotion, by the use of which sufferers from rheumatism can obtain immediate comfort and ultimate cure."

THE PATHOLOGY OF THE PEARL.

An interesting account of the Ceylon pearl fisheries is given by Mr. S. Muttiah in the February number of the *London Hospital Gazette* together with many particulars about the industry and the methods of conducting it. The theory of pearl formation adopted by the Royal Society's Commission 10 or 12 years ago was that of a pathological secretion formed round some foreign body, such as a grain of sand; and such an explanation is certainly plausible, in view of the fact that only a small percentage of the oysters from the Ceylon beds contain pearls. Two other theories are mentioned by Mr. Muttiah: one ascribes the process to the irritation of the dead larvæ of a parasitic worm (*tetrarhynchus*); the other to a disease of the muscles of the oyster somewhat analogous to the formation of gall-stones in human beings. All three views agree in regarding the pearl as pathological, not physiological. We are not told how differences in colour are explained, especially such very marked differences as in the curious pink, yellow, and often very irregularly shaped pearls which are found on the Bahama banks in another species of mollusc Nor has science yet succeeded in improving on Nature's wasteful and inefficient processes by rendering possible the artificial encouragement and control of pearl formation; but stranger things have happened, and this is by no means beyond the bounds of possibility. The fishing on the Ceylon banks is conducted in the most primitive way by natives of at least half a dozen races, of whom the Arabs are said to be able to stay longest under water—namely, 60 to 85 seconds As a rule, it appears, the average diver does not suffer materially in health from his occupation, though deafness is very common The usual maximum depth worked is seven fathoms, at a pressure of about two and a quarter atmospheres On one occasion when a deeper bed was fished at nine fathoms five men collapsed, of whom two died, but, as a general rule, the divers live as long as others of the coolie class Years of good harvest alternate with lean ones, thus, in 1814 the catch yielded £105,187, while in 1815 the revenue was £584 In 1906 the Ceylon Government leased the fishing to a London syndicate for a rent of £310,000 per annum, but a couple of years later it was found that beds of young oysters which should have been left to grow had been destroyed, and it is understood that the syndicate is seeking to be released from the agreement

THE RECORD PACE.

ON Saturday last, on the Brooklands track, Mr Percy Lambert, an amateur, drove a Talbot 25 h p car 103¾ miles in an hour It is reported *that this is the first time in the history of the world* that a human being has travelled 100 miles on land within 60 minutes Probably there are not many human beings who desire such a distinction

HEALTH AND SANITATION IN TRINIDAD AND TOBAGO

A REPORT on the Blue Book of the Colony of Trinidad and Tobago for the year 1911-12 gives the estimated population as 340 223 The number of births recorded during the year was 11,674 as compared with 11,570 in 1910-11 The deaths numbered 7870, as against 7448 *in the preceding year* The *birth rate*, calculated on the mean population is shown to be 34 65 per 1000 and the death rate 23 36 The principal causes of death during the year were diarrhœa and enteritis, 951, malarial fever, 722, typhoid, 87, pulmonary tuberculosis 631, other forms of tuberculosis, 62, bronchitis, 372, pneumonia 306 Nearly all the medical officers report favourably on the general health conditions of their districts during the year there being little infectious disease and no unusual prevalence of endemic disease A mild type of measles, unattended by any deaths occurred in some districts Five cases *of* bubonic plague occurred during the year, four being fatal Precautionary measures against this disease are actively carried on at all *times*, and *during* the *year* 22,658 *rats* were caught, of which 16 682 were bacteriologically examined for evidence of plague infection Only one infected rat however, was discovered No case of yellow fever occurred, indeed there has been no case since April, 1910 The work of mosquito reduction is regularly carried out and the good results obtained are sensibly felt in Port of Spain where 131 convictions for breach of the mosquito regulations were obtained and fines amounting to £26 recovered

Some of the district medical officers refer to the inadequate supply of water in their districts leading to the use of sources of supply unfit for domestic purposes more especially during the prevalence of severe droughts and thus giving rise to diarrhœal and dysenteric affections The water supply in many districts is very deficient in the dry season and the question of the provision of additional sources of good water presents great difficulty Borings have been made by the Government with indifferent success, and the matter is receiving *attention The Colonial Hospital, Port of Spain*, is the *most* important in the colony The number of patients admitted at this institution during the year was 6218, the daily average in hospital being 304 There were 718 deaths Of the patients discharged, 2110 were cured, 3151 relieved, and the condition of 250 not improved At the San Fernando Hospital 3091 persons were admitted, the daily average of patients being 97 The deaths numbered 374 Of the patients discharged 552 were reported as cured, 2009 as relieved, and 180 as not improved There are district hospitals maintained by the Government at Tobago, Arima, *St Joseph*, Tacarigua, Couva Princes Town, and Cedros there are also temporary hospitals available when required, at Chaguanas, Sangre Grande, and Mayaro There are two hospitals specially devoted to the treatment of persons suffering from yaws in *Trinidad* and Tobago In connexion with this disease extraordinarily good results were obtained at the St Augustine Yaws Hospital by Dr H M Alston and Mr. W F Cleaver by the use of salvarsan Out of 500 cases injected in 1911, 498 were cured, 409 with one injection, 75 after two injections, and 14 after three injections The Leper Asylum, situate at Cocorite near Port of Spain, contained 225 inmates at the close of the year There had been 90 admissions during the year, 40 discharges and 38 deaths

The mean rainfall for the Colony of Trinidad and Tobago for the year 1911, *compiled from observations taken* at 85 stations, was 62 44 inches, as compared with 82 65 inches in 1910 (an exceptionally wet year) The mean maximum temperature for the year at the St. Clair experiment station, Port-of Spain, was 86 1, and the mean minimum temperature 68 5°. The climate of Trinidad is not unhealthy for a tropical colony situated so near the Equator. From January to April the heat during the day is not excessive; the nights are cool, and occasionally even chilly, during the whole year. Europeans who take reasonable care of themselves enjoy excellent health in almost every part of the colony In a few malarial spots special care is necessary to avoid contracting fever, but these places are well known and are limited in extent

SHORT SEA TRIPS FOR EARLY HOLIDAYS

THOSE who find it necessary or desirable to take a holiday early in the year—and their number seems to be increasing—may be recommended to consider the 15-day sea trips to Gibraltar and the Mediterranean which the Orient Line has organised. In this way a pleasant "change" can be obtained at this season of the year, and a brief visit to Spain or the Riviera is well worth making The man of modest means will find the second saloon accommodation quite good as well as extraordinarily cheap

A NEW SPANISH MEDICAL JOURNAL

A NEW medical monthly has just made its appearance in Valencia under the title *Policlinica* This first number contains original articles on Tuberculosis in Children and its Treatment by Immunising Bodies (Spengler's method), by Dr D Aguilar Jordan; Pericardial and Perihepatic Symphysis, with coloured illustrations, by Dr. Pastor Reig, and on Physiological Regeneration of the Blood in Anæmia, by Dr. Fillol Also a considerable number of synopses of articles in foreign medical journals

A MEDICAL OFFICER OF HEALTH FOR EAST LONDON, SOUTH AFRICA

WITH regard to this appointment, applications for which are invited in our advertisement columns, we have received a letter asking intending applicants to communicate with Dr J Tremble, secretary of the Border branch of the British Medical Association, at Frere Hospital, East London

THE UNIVERSAL ESPERANTO MEDICAL ASSOCIATION.

Mr. G Jameson Johnston, professor of surgery in the School of the Royal College of Surgeons of Ireland, has been elected President of the Universal Esperanto Medical Association in succession to the late Professor Dor, of Lyons

A DIARY OF CONGRESSES

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement The following Congresses, Conferences, and Exhibitions are announced —

March 1st (University of London) —Eugenics Education Conference
" 17th-20th (Paris) —International Congress of Physical Education
(Easter week) (Berlin) —Fourth International Congress for Physiotherapy
March [illegible] the German Association
" [illegible] Congress of the German
" 29th and 30th (Berlin) —Ninth Congress of the German Roentgen Society.
April 3rd-9th (London) —International Congress of Historical Studies
" 6th-12th —Health Week
" 22nd-25th (London, Horticultural Hall) —Nursing Conference [illegible]
" [illegible]
May [illegible] of the Royal

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

Thursday.—Mr. C. F. Jenkin and Mr. D. R. Pye: The Thermal Properties of Carbonic Acid at Low Temperatures (communicated by Sir J. A. Ewing).—Mr. E. Roberts: Re-reductions of Dover Tidal Observations, 1883–1884 (communicated by Lord Rayleigh, O.M.).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday.

Section of Odontology (Hon. Secretaries—Stanley P. Mummery, Robert McKay): at 8 p.m.

Mr. G. H. Berwick: Restoration after Surgical Operations.

Casual Communications:

Mr. A. E. Ironside: Hypertrophy of Gums in Child. Patient Present.
Mr. L. Stanley Kettlewell: Fibroma of Maxilla.
Mr. H. J. Relph: Odontome.
Mr. F. J. Smyth: Misplaced Mandibular Canine.

Tuesday.

Section of Medicine (Hon. Secretaries—Robert Hutchison, H. Batty Shaw): at 5.30 p.m.

Papers:

Dr. F. Parkes Weber: [illegible] Secondary Polycythæmia in [illegible]
Dr. Gordon R. Ward: [illegible]

Friday.

Section for the Study of Disease in Children (Hon. Secretaries—H. S. Clogg, F. Langmead, P. N. Blake-Odgers): at 4.30 p.m.

Cases:

Dr. F. Parkes Weber: Flexion and Ulnar Deflection of the Fingers.
Dr. F. G. Crookshank: Mongoloid Child of European Descent.
Mr. J. E. Adams: Two Cases in same Family of Congenital Coalescence of Radius and Ulna.
Mr. Douglas Drew: (1) Plastic Operation for Contraction after Burn of the Hand; (2) Plating for Separation of Lower Epiphysis of Femur, done 3 Years Ago, Plate not removed; (3) Large Lymphangioma removed from an Infant of 9 Months.
Mr. D. [illegible] Years ag[illegible]
Dr. E. [illegible]

Paper:

Dr. H. Charles Cameron: Summer Diarrhœa and Summer Heat.

Section of Epidemiology (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 p.m.

Papers:

Dr. William Butler: Measles.
Mr. B. Glanville Corney, I.S.O.: A Note on an Epidemic of Measles at Rotumá, 1911.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday.—8.30 p.m., Mr. Ralph Thompson: Unilateral Renal Lesions, to be followed by Mr. T. Walker and others.—Dr. O. Kauffmann: Some Experiments on the Urinary Excretion of Potassium Iodide and their Clinical Significance.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures, original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO, 51, Fifth Avenue, New York, U S A

By advanced cases I do not mean merely those of long duration, for, as a matter of fact, the cases in which operation can be undertaken with least risk include some in which the disease has been in progress for several years. I refer to the acuteness of the intoxication and the presence of secondary degeneration of viscera, especially of the heart, rather than to the duration of the disease.

Those who have studied in detail the literature of the subject, and more particularly those who have had the opportunity of seeing many cases before and after operative treatment, cannot fail to be struck by two main facts—firstly, the danger of the operation as often performed; and, secondly, the undoubted benefit that results in a large proportion of cases.

We have to consider how far the benefit justifies the risk. At the outset of our inquiry we are met with difficulties. For instance, what is exophthalmic goitre? If we include under this term only the well-marked cases, with all the usual signs and symptoms, we shall find that the operative mortality is very much higher than it is if we follow the tendency of the present day and allow the term to embrace many cases whose claim to this position is at least very doubtful. For instance, a patient with an ordinary parenchymatous goitre, or an adenoma, or cyst of the thyroid, who has some tachycardia and complains of palpitation, is regarded by some observers as a case of mild exophthalmic goitre, by others as an instance of hyperthyroidism, and therefore belonging to the same class, despite the fact that the majority of these cases, if allowed to progress, never develop exophthalmos or the more serious characteristic symptoms of the disease. The validity of these claims I discussed fully in my last lecture, and I will not now enter into the question again. The point which I wish to emphasise is this: that the mortality statistics of two operators equally skilled, and operating in exactly the same manner, will differ enormously if the one includes in his statistics only such cases as come strictly within the limits of the first group, while the other does not hesitate to include all the far less serious forms that constitute the second group.

We should be very careful, then, in drawing conclusions from mortality statistics, as given in published records, unless we know to what class of cases the statistics refer. Probably the only safe test is the pathological one. As I have shown in my first lecture, every case of true exophthalmic goitre is accompanied by definite pathological changes in the thyroid, which should be recorded if the statistics are to be of any real value. Mortality statistics based upon such pathological findings are rare in medical literature at the present day. Another difficulty with which we meet is the fact that cases of Graves's disease do not pursue a uniform and progressive course. While one case will progress gradually from bad to worse, and perhaps even end fatally, in another the disease, for no apparent reason, will come to an end spontaneously. If we knew that every case if untreated would get steadily worse, the dangers of the operation would require less serious consideration. Nobody hesitates to operate for even the worst case of strangulated hernia, because the risk to life if no operation is performed is far greater than the risk of the operation. But with a disease that is not necessarily fatal we should inquire very carefully into the risks of the proposed operation before we recommend it.

Results of Medical Treatment

First, let us consider the mortality of cases of Graves's disease that are treated medically. We find that it is not very high. Dr. Hale White has investigated carefully the after-histories of a large number of patients, and concludes "that the mortality among sufferers from exophthalmic goitre was about twice that among the general population for the same age and the same time."[2] Dr. Hector Mackenzie,[3] after a very large personal experience of the subject from the medical point of view, came to the conclusion that of cases treated on broad general medical lines about 25 per cent. made a good recovery; another 25 per cent. were very much improved, and, although not cured, the patients were in fair health and able to follow their occupations; another 25 per cent. became more or less chronic invalids; while the remaining 25 per cent. lost their lives from the disease itself, after a longer or shorter illness. Dr. George Murray[4] has expressed the opinion that "the prognosis usually given in text-books is too pessimistic, as a very considerable number of cases do either completely or partially recover without operation."

There can be no doubt, however, that medical treatment really does very little to influence the course of the disease. Most of the patients who recover do so only after a prolonged period of ill-health and often of great distress. The sufferings of patients with well-marked Graves's disease are usually (although not always) so great that they are only too ready to undergo any operation which offers them a chance of relief.

The Mortality of Operation for Graves's Disease.

When we come to consider the mortality of the operation for exophthalmic goitre we find that it is very difficult, indeed impossible, to make any definite statement. So much depends upon the individual operator, upon the method of operating, upon the nature of the operation performed, and especially upon the selection of cases submitted to treatment. Mr. Wilfred Trotter, taking the experience of representative surgeons on the continent, has expressed the opinion that "out of the first 50 cases of any given surgeon he will usually lose five as a direct result of the operation," and that this 10 per cent. mortality is usually considerably reduced in a surgeon's later work, and "is no doubt to some extent to be regarded as a measure of the difficulty in acquiring the special kind of knowledge which goes to successful operating on these cases." This seems to me to be a very reasonable estimate, for though it is easy to find series of cases in which the mortality is a good deal higher than this, yet it must be remembered that statistics often include cases operated upon years ago, when technique was by no means as good as it is now, and when much less care was taken in the choice of cases for operation. Thus the Mayos, who obtain such brilliant results at the present day, lost 4 out of their first 16 patients, von Eiselsberg 3 out of his first 4, and so forth.

The number of patients upon whom I have myself operated for exophthalmic goitre is comparatively small, amounting up to the end of 1912 only to 27. These were all cases of undoubted Graves's disease, in which all the classical symptoms, including exophthalmos, were present, mostly in a very marked form. Of these 26 patients, 2 have died as the result of operation, 1 in 1901 after simultaneous ligation of three arteries, and 1 in 1911 after a bilateral excision. To these cases I shall refer later. The patient with severe Graves's disease, who died before I commenced the intended operation of ligation of a superior thyroid artery, and whose case I described fully in my last lecture, is not included in these statistics. But on looking through the notes of my last 351 goitre operations I find there were at least 33 other patients of whom it is stated that rapidity of pulse, tremor, nervousness, or some similar symptom was one of the principal reasons for operation. Most of these cases would undoubtedly be classed as instances of exophthalmic goitre by those who are not so rigid in their definition of the disease as I am myself. Among these there were no deaths; nor were there any deaths among the cases of like nature in my first 400 operations, which I have already published in full elsewhere, and to which I make no further reference.

SELECTION OF CASES AND TIME AND METHOD OF OPERATION.

Dr. Charles Mayo, writing in July, 1912, states that within the last year he and his colleagues have operated on a consecutive series, between deaths, of 278 cases of exophthalmic goitre without a death, and goes on to say that he believes that this marked improvement upon the statistics of his early cases has been caused by taking into account the so-called "factors of safety" in connexion with the examination, preparation, and operative treatment of these patients. In order to ascertain as far as possible what these factors of safety really were, and to see for myself what cases were actually being operated on by those surgeons who have had the largest experience in the world of the surgery of exophthalmic goitre, I paid in the course of last year visits to the famous clinics of Berne and of Rochester, Minnesota.

At Berne I was somewhat unfortunate in my experience, as during the week I spent there Professor Kocher did not, as it happened, operate on any case presenting symptoms of Graves's disease. I saw several cases upon whom operation had been already performed, and I saw a number of operations for ordinary goitre which gave me an opportunity of seeing his technique, which is the same, I was told, for the exophthalmic variety. This did not differ in essentials from that at Rochester or from that of most surgeons who have much to do with goitre operations, which, indeed, is not surprising, since it is largely from Professor Kocher that most of us have learnt our technique.

[3] Debate at the Royal Society of Medicine, 1912, vol. v.

[4] Ibid., THE LANCET, Feb. 24th, 1912, p. 490.

At Rochester, during the two separate weeks that I spent there, I had the opportunity of seeing numerous operations upon exophthalmic as well as upon ordinary goitres. I found not only the Mayos themselves, but their colleagues, Dr. Judd, Dr. Beckman, and Dr. Plummer, and the pathologist, Dr. Louis Wilson, all most willing to explain fully in the most open manner exactly what they were doing, and to afford me every opportunity of seeing their patients before, during, and after operation, and the pathological specimens themselves. It is difficult to speak too highly of the care exercised in the examination and preparation of patients before operation, of the operative technique, or the scrupulous accuracy with which their records are kept.

Dr. Plummer, the physician, examines with the most minute detail every exophthalmic goitre patient, in consultation with one of the surgeons, and recommends the suitable cases for operation, or, if necessary, for preliminary medical treatment. He told me that he considered it of the greatest importance to gauge the degree and stage of the thyroid intoxication, and to avoid operation while it is at its height. From the examination of some hundreds of patients he has been able to establish the fact that in the great majority of cases the disease runs a fairly definite course as regards the severity of the intoxication. "If the average course of the disease be represented by a curve, the greatest height of the intoxication is found to be reached during the latter half of the first year, and then rapidly drops to the twelfth month. In many instances it reaches the normal base line during the next six months; more often it fluctuates with periods of exacerbation for the next two to four years. Secondary symptoms and exophthalmos may remain, but the active course rarely continues over four years without distinct intermissions. The ascent may be gradual, sudden, or irregularly marked by many secondary curves.[5]

Dr. Plummer tells me that he considers the operation is done with the greatest safety either quite early in the disease or much later, when the period of greatest intoxication has passed by. He also informs me that the average duration of the disease at the time of operation at Rochester is about two years. There are, of course, some cases upon whom no operation of any kind is performed. In determining the degree of intoxication Plummer and Mayo attach much importance to the amount of mental excitability and muscular weakness which are present; the latter is often very marked in the quadriceps, and is easily tested by asking the patient to step up on to a low stool. Dilatation of the heart exceeding one inch they regard as a serious condition, while that extending to an inch and a half may be expected to give a percentage of unavoidable mortality for the radical operator of partial thyroidectomy. Dr. Plummer is, I believe, about to publish more fully his extensive and valuable observation on these points.

The dangerous cases, in which operation in my opinion should *not* be undertaken, are those acute ones in which there is much thyroid intoxication as shown by great excitability, mania, or muscular weakness, or who are suffering from any acute inflammatory infection such as bronchitis; secondly, those in which marked degenerative changes have taken place in the viscera, especially the heart and kidneys. Albuminuria, glycosuria, diarrhœa, a constantly irregular pulse, and low blood pressure are all conditions which should lead the surgeon at least to postpone operation; and if these conditions cannot be remedied by medical treatment, operation should not be performed at all. Of all chronic complications, marked dilatation of the heart is perhaps the most common and the most serious.

It is in the severe type of case, in which thyroidectomy is likely to be very dangerous, that ligation of arteries may sometimes be performed with advantage. Ligation of the superior thyroid artery is chiefly useful as a means of ascertaining the susceptibility of the patient to operation rather than as a means of cure. In any case in which it is doubtful whether the patient is fit to undergo the larger operation of partial thyroidectomy, it is well to begin with a preliminary ligation of one superior thyroid. If the reaction from this is slight, partial thyroidectomy can probably be carried out with safety a week or two later on the other side. If the reaction be severe, the best plan is to tie the opposite thyroid before resorting to thyroidectomy, or possibly to be content with ligation alone. Dr. Charles Mayo, who has had a very large experience of ligation, considers that the reaction after ligation of one superior thyroid artery is about three-fourths as severe as bilateral ligation, but that the missing fourth is an element of safety. The subsequent ligation of the opposite artery a week or two later is a much less severe proceeding.

I cannot conclude this part of my subject without referring to the brilliant work of my friend, Dr. T. P. Dunhill, of Melbourne, who has had a very large operative experience of exophthalmic goitre, and who is one of the most enthusiastic advocates for operation in this disease. Dr. Dunhill is perhaps more willing to operate on really bad cases of the disease than any surgeon I know, and his results are certainly admirable. For details I must refer to his introductory address, which opened a valuable debate on the treatment of Graves's disease at the Royal Society of Medicine just a year ago.[6] Both the address itself and the long debate which followed, in which most of the principal authorities on the subject in this country, surgeons, physicians and anæsthetists, took part, are well worthy of careful study. I may add that I have quite recently received a letter in which he states, in answer to a question of mine, that he has in no way altered his views, and that he continues to operate on large numbers of exophthalmic cases.

THE ADVANTAGES OF OPERATION.

We turn now to the advantages of operation. That patients do derive great benefit from operation in nearly all cases there can be little or no doubt. The testimony of all surgeons who have had much to do with exophthalmic goitre is overwhelming on this point. Of my own operation cases, with the exception of the two that died, there is not one that has not benefited by the operation, although in one or two the benefit has not been great, and in one case at least there has been a slight relapse.

Patients undoubtedly do improve in a manner that is not seen, as far as I know, after any other method of treatment. Even after a single ligation they nearly always say they feel better. After double ligation the benefit is usually still greater. A lady whom I saw at Rochester several weeks after Dr. Charles Mayo had tied both superior thyroids for severe and pronounced exophthalmic goitre said to me: "When I came here four months ago I was so wretched and miserable that I did not care whether I lived or died; now I feel well and happy"—and certainly she looked it.

A case of my own is that of a lady, aged 39, who had had all the classical symptoms of Graves's disease for nearly two years when I first saw her. After two months' preliminary treatment I removed the right lobe in May of last year. In October she wrote to me as follows:—

> I feel an absolutely different woman since you operated upon me for exophthalmic goitre in May last. My general health is good, and my relations tell me that never in my life have they seen me look so well. The nervousness has quite disappeared, also the trembling, and my eyes are normal, while my colour is fresh and clear. The palpitations have quite ceased, and altogether I feel like one "risen from the dead," as it were.

Another patient, a woman, aged 34, with typical exophthalmic goitre, from whom I removed one lobe (shown to you at the last lecture), writes to me four months later:—

> I am glad to say I am feeling much better now. Previous to the operation I had suffered from great heats, palpitation of the heart, sleeplessness, and nervousness, but all these symptoms have almost disappeared. Of course, I have to be very careful, as any over-exertion causes my heart to beat rapidly. I have very good nights, and have regained all lost weight, from 8 st. 2 lb. to 9 st. 6 lb. It is splendid to feel so much better, and I hardly know how to thank you for all you have done.

I could easily multiply examples such as these. Patients in whom emaciation is a feature of the disease, as in the above case, and I need hardly say it is a common feature, often put on flesh rapidly after the operation, although there may be an initial loss of a few pounds as its immediate result.

---

[5] Factors of Safety in Operating for Exophthalmic Goitre, by Charles H. Mayo, Journal of the American Medical Association, July 6th, 1912, vol. lix., pp. 26, 27.

[6] THE LANCET, Feb. 17th, (p. 422) and 24th (p. 503), and March 2nd (p. 576) and 16th (p. 724), 1912.

Perhaps the most striking examples of the benefits of operations are to be seen in the case of men who, on account of their complaint, have been quite incapacitated from work. Thus I may cite the case of a man from whom I removed the right lobe of the thyroid for typical Graves's disease in June last. For ten months before the operation he had not been able to do any work. Yet when I last saw him a few days ago he told me that he felt so much better that he was now hard at work *as a scaffolder. He still shows* symptoms of his disease, but he is at any rate now able to earn his living.

In estimating the actual amount of benefit that follows operation in any given case we must bear in mind the fact that in exophthalmic goitre the symptoms are of a particularly subjective character, and that the functional disability of the patient does not bear a constant relation to the physical signs; for example, a patient may have all the cardinal signs in such a well-marked degree that there is not the least doubt as to the diagnosis, while he may complain of nothing but occasio[illegible] do his work. Whereas [illegible] less distinct signs may [illegible] invalid. When we examine a patient a few months after operation we sometimes find that he has still some exophthalmos, tachycardia, and enlargement of the thyroid gland, and on asking the usual questions we are told that he is still subject to palpitation, and to a certain amount of breathlessness on exertion. Then, while we are preparing to write the case down a failure, we are surprised to find that, in spite of all, we are dealing with a very grateful patient, who declares that he is much better, and is able to lead a very much more active life than formerly.

I think there can be no doubt that operation does in many instances relieve the subjective distress which is so characteristic of the disease, and although such improvement, when unaccompanied by much obvious change in physical signs, is not of much value for statistics, it is certainly a practical point which ought not to be overlooked. A good instance of this is afforded by the case of a woman, aged 26, with pronounced and typical exophthalmic goitre, from whom I removed half the thyroid in July, 1909, and whom I have been seeing from time to time since that date. She still has exophthalmos, and she still has some tachycardia, but always expresses herself as being very much better for the operation. When I last saw her a week or two ago, seeing that she still had the objective signs of the disease, I asked: "In what way are you better?" And her reply was: "Well, *before the operation I was frequently laid up and away from* my work, and now I never am."

THE QUESTION OF ANÆSTHESIA.

With the much-discussed question of anæsthesia I must deal briefly. Much depends upon the anæsthetic and much upon the patient. My own feeling upon the matter is that for exophthalmic goitre chloroform is more dangerous than ether, even when administered by a highly skilled anæsthetist; ether given by a closed method is much more dangerous than ether on an open mask; while the method [illegible]

The main advantage of local analgesia is that the patient can drink freely during and immediately after the operation. This certainly diminishes the tendency to excessive post-operative tachycardia, which is one of the principal dangers. The absence of post-anæsthetic vomiting renders recurrent venous hæmorrhage less likely to occur, although if sufficient care be taken with hæmostasis the strain of retching ought not to have any bad result. The principal disadvantage is the psychic effect upon the patient if very nervous; a general anæsthetic may be less injurious than the nervous excitability caused by dread of the operation. It is important, I think, not to operate upon any one who is in a condition of great alarm. In hospital practice, where the patients can talk to one another and the effects of previous operations on others can be seen by those about to undergo a similar experience, these fears can usually be quickly allayed. I find that, as a rule, before the day arrives the patient has lost much of her dread and is eager to submit to operation. Crile's method of "stealing the gland" by administering an anæsthetic on several occasions before the real operation is undertaken, so that the patient does not know when the operation is to be performed, does not seem to me to have much in its favour, and I have never employed it.

Von Eiselsberg[7] states that at first when operating for Basedow's disease he was careful to avoid the use of general anæsthesia, but that of late he had been employing it in some cases of very nervous patients, in whom otherwise the danger of shock seemed to him to be too great. I think that most surgeons would agree that, however strongly they advocate the use of local analgesia, there are cases in which a general anæsthetic must be employed.

OPERATIONS FOR EXOPHTHALMIC GOITRE.

I come now to the various operations which may be performed for exophthalmic goitre.

Exothyropexy and Operations on the Sympathetic.

With regard to exothyropexy and operations on the sympathetic, I cannot believe that either of them is worth doing, and I need not say much about them. Operations upon the sympathetic are performed by very few surgeons. Jaboulay and Jonnesco are the two who have had most experience of this method. When at Bucharest two years ago I was informed that the latter still practised the operation, but I did not see any of his patients.

Jaboulay[8] in 1911 wrote a good account of 31 patients on whom he had operated. Three were mild cases, all the rest were of "true typical exophthalmic goitre"; none were of the so-called "basedowified" goitre, what we should call secondary Graves's disease. In 21 cases the superior cervical ganglion was removed together with part of the main [illegible]neath it; in nine cases the [illegible] usually just below the [illegible]e middle ganglion; in one case mere stretching of the sympathetic was the operation performed. Of patients operated upon before 1900, five died from septic complications (pneumonia and erysipelas) due to bad hospital conditions. Since 1900 only one patient has died, and this one had the usual hypertrophy of the thymus, to which the death is attributed. Of the 25 patients who survived the operation, 1 cannot be traced; 2 were in perfect health four and six years after operation, but have since been lost sight of; 12 were living at the time of the report; 7 after having been notably improved by the operation have since died, mostly from four to nine years afterwards, from an intercurrent disease; 3 died as the result of a further operation upon the gland itself, intended to complete the cure. *Eliminating the cases that cannot be* traced, and those that have been operated upon within two years, he says that 15 out of 21 have survived for more than four years, and of these 15 there are 9 still living 12 and 14 years after. His conclusion is that the patients can live a long time after the operation, and that this proceeding arrests or cures the diseas[illegible] cases of complete cure. [illegible] point that in no case has [illegible] ance in the eye or face as a consequence of his operative interference with the sympathetic.

These results do not seem to me to be very encouraging. I have never performed this operation myself, nor do I feel at all inclined to recommend it. The only case of the kind that has come under my own observation, although not in my own practice, was that of a young woman with well-marked signs who died within a few hours of the operation with the usual symptoms of so-called hyperthyroidism, restlessness, excessive tachycardia, and a very high temperature.

Heinlein[9] reports an interesting case on which exothyropexy was performed. The patient had exophthalmos, tremor, emaciation, and a pulse-rate of 150. The author decided to do a partial thyroidectomy. Local anæsthesia was employed, and the right upper and two lower arteries were first tied. The operation proved very difficult, and when it had lasted two hours the man's condition was such that Heinlein concluded it rapidly by leaving a portion of the gland exposed instead of removing it. The portion exposed dried up gradually, and at the end of six months a prominence of the size of half a hen's egg remained, while all the symptoms had completely vanished, the pulse-rate being 60 and the nutrition good. In spite of the success of this case the author does not recommend exothyropexy, but considers partial thyroidectomy to be the operation of choice.

Ligation of Thyroid Arteries.

Ligation of arteries has, in my opinion, a well-established position in the surgery of exophthalmic goitre. Ligation of one superior thyroid artery has the advantage that it is a comparatively small operation, that can often be performed with more safety than a hemithyroidectomy. Even bilateral ligation of the superior thyroids is less severe than partial thyroidectomy. Ligation of the inferior thyroid is, however, a difficult and somewhat severe procedure, and should, I think, rarely be adopted. Ligation of both superior and one inferior arteries may be quite as severe as removal of half the gland. It may, perhaps, be advisable in some cases of large goitres in very thin people, since in thin subjects the mechanical difficulties of tying the inferior artery are less.

Here is a photograph of a man aged 32, one of the most advanced cases of Graves's disease I have ever had to deal with. He had well-marked exophthalmos, palpitation, rapidity of pulse, tremor, emaciation, diarrhœa, and extensive bronzing of the skin. He was so nervous and excitable that for some months he had been wholly unable to follow his occupation, that of a clerk. He told me that he was anxious to undergo any operation, however dangerous, which would afford him any prospect of relief. In July, 1901, I tied both superior and one inferior thyroid arteries, under local anæsthesia; he stood the operation well, and within a few weeks a most extraordinary improvement set in. His palpitation vanished almost entirely, his pulse-rate fell markedly, the diarrhœa disappeared, and he lost practically all his subjective symptoms. He was able after a few weeks to return to work, and although he never completely lost the exophthalmos and was liable to occasional attacks of palpitation during excitement, he was practically well and always expressed himself as most grateful for the amount of benefit he had received from the operation. When I last saw him, 14 months after the operation, he told me that he felt quite well and "was able to do his work as well as anyone else." His weight, which before operation was only 5 st. 4 lb., increased to 9 st. 7 lb. He remained at work until the day of his death some time afterwards. He died suddenly in an epileptic fit. He had been subject to epilepsy for years before the exophthalmic goitre began.

Shortly after this I did precisely the same operation on a young woman with ordinary well-marked exophthalmic goitre of about three months' duration, but she died in 36 hours with typical symptoms of hyperthyroidism. I have no doubt now that in this last case I did too much. The case was too acute for simultaneous ligation of three arteries. At the present time in such cases as the above I should proceed more slowly, tying not more than one or possibly two arteries at a time.

Simultaneous ligature of all four arteries I have never performed, and I doubt if it is a justifiable proceeding. It is quite as severe as hemithyroidectomy, and may be followed by myxœdema or tetany.

It must not be supposed that ligation of even a single superior artery is wholly free from risk. On the contrary, it has a distinct mortality. Thus, of the 17 deaths in Kocher's large series 5 occurred after ligation of arteries. It has been objected by some that, as the benefit conferred on the patient is much less than that obtained by thyroidectomy, and as the risk is appreciable, it is not worth doing. But when we compare the risks of ligation with those of thyroidectomy, it must be remembered that it is precisely in the worst cases that ligation is usually performed, cases in which the prudent surgeon would probably not think it right to do the larger operation.

As regards the operation itself, in a thin subject with a fairly large goitre—that is, one in whom the artery is large and fairly superficial—the operation presents no great difficulty. The chief trouble is from the overlying superficial veins, which sometimes are numerous and easily wounded. An oblique incision is made along one of the natural creases of the skin. The best guides to the artery are the omohyoid muscle, at the outer border of which it is usually tied, and the upper pole of the gland itself. If any difficulty is experienced in finding the latter I have found it useful to ask the patient to swallow; the upward movement of the gland will render its detection more easy. The pulsation of the artery itself is also a good guide, but care must be taken not to mistake for this the pulsation of the main carotid or one of its branches. It is best to tie the artery close to the gland, or even to include in the ligature the upper pole of the gland itself. By this means the chance of a collateral circulation being established is rendered less likely. The superior thyroid generally gives off a large branch close to the apex of the gland, and the ligature should include this branch. I think it best not to separate the artery from the vein, but to tie both in a common ligature together with the lymphatics. The wound should usually be closed with buried catgut sutures, without drainage.

Ligation of the inferior thyroid artery is a very much more difficult operation. It may be performed either through a long incision at the anterior border of the sternomastoid, in which case numerous large veins will have to be secured, or at the posterior border of that muscle. The latter method is that which I have myself adopted in the few cases in which I have performed this operation. It involves less disturbance of the gland and less trouble with the veins. But a deep and careful dissection is required, as the artery lies close to many important structures, and a good knowledge of anatomy is very necessary.

Partial Excision of Thyroid Gland.

I come now to the operation of removing part of the thyroid gland, which should be the operation of choice for exophthalmic goitre. It is important that the operation should be performed as quickly as is consistent with thorough hæmostasis. The utmost care should be taken to prevent hæmorrhage by securing at once with forceps every bleeding point. The main superior thyroid vessels should be tied as soon as possible, and then, after the other thyroid veins have been dealt with, the main inferior artery should be ligated with its veins. For exophthalmic goitre ligation of the main artery well outside the recurrent nerve is preferable to tying the branches close to the gland. Access to the artery is much facilitated by lifting the lobe up and drawing it forwards and inwards. But on account of the firmness and solidity of the gland it is often much more difficult to do this with an exophthalmic than with an ordinary goitre. With both classes of goitre, but especially with the exophthalmic variety, the difficulty is greatly increased if the isthmus is very thick, as it often is.

I should like here to emphasise once more the necessity for avoiding undue hæmorrhage. Next to asepsis, efficient hæmostasis is the most important point in the removal of exophthalmic goitre. It is loss of blood, more than anything else in my opinion, which is the cause of the post-operative mortality in these cases, in the hands of surgeons whose asepsis is beyond reproach.

It is customary to lay great stress upon the avoidance of bruising or crushing of the gland. But in spite of the opinion of Dr. Dunhill, of whom I speak with the greatest respect, I believe that this danger is greatly overrated, and is much less than that of hæmorrhage. A recent writer[10] states that Kocher cures all cases of Graves's disease by thyroidectomy with a mortality of 2½ per cent., and that his success depends on the delicacy of the operation, so that no secretion is forced into the circulation. The first part of this statement is certainly not borne out by Kocher's own publications. The second part is, I venture to think, a most dangerous doctrine. The writer makes no mention whatever of the many other precautions on which Kocher rightly lays so much stress, and if anyone should be led to operate on the assumption that the one thing essential was manipulative delicacy, he would very soon meet with disaster. Albert Kocher states quite definitely that he does not consider the attacks of acute thyroidism to be the result of pressure on the gland, since if this were the case symptoms would set in immediately after operation, whereas not seldom they do not begin until from 12 to 24 hours after operation. He mentions also the fact that massage of the gland has been used by Weir Mitchell in treatment without any bad results. With his opinion I entirely concur. I do not think that the so called attacks of acute thyroidism are to be explained solely, if at all, by mere manipulation I may here add that by far the most important point in the after treatment is the administration of large amounts of water immediately after operation, either by the mouth or by the rectum, or even subcutaneously in the form of saline solution

---

[10] Practitioner, December, 1912.

Extent of Removal of Gland

The question how much gland shall be removed is difficult to answer, much depends on the skill of the operator and his familiarity with the operation For most cases it is best not to remove more than one lobe If necessary, more may be removed subsequently But if too much be removed at once [illegible] I have myself [illegible] each lobe, but [illegible] the goitre was not a large one, the total removal being only a little over 6 oz (182 grm) The patient was very greatly benefited, and may be said to be almost completely cured But I now think, nevertheless, that I did too much, and that the patient ran an unnecessary risk The only case that I have lost from removal of an exophthalmic goitre was that of a lady aged 33, who had had well marked Graves's disease for four years I kept her in bed for a fortnight, and then removed nearly all the right lobe without having done a preliminary ligation Finding that she stood this part of the operation well, I was tempted to go on to removal of half the left lobe The increased duration of the operation, with the additional hæmorrhage that was necessarily involved, proved too much for her, and she died suddenly three hours after the operation I did not at that time realise sufficiently the difference between operating upon an exophthalmic and upon an ordinary parenchymatous goitre, in the latter class of case I have done far larger bilateral operations many scores of times without the least fear or anxiety

I may here allude to two points of some practical importance, one is that the removal of even half the second lobe in any goitre operation is likely to be a more severe proceeding than complete removal of the first lobe For the simple reason that in the complete removal of a lobe the hæmorrhage can be greatly lessened by ligation of both thyroid arteries of that side In the partial removal of the [illegible] rmissible, and the cutting [illegible] tissue may lead to more [illegible] The other point is that operations upon exophthalmic goitres are undoubtedly more severe and more dangerous than operations upon ordinary goitres of the same size in patients of the same age Upon this point practically all operators of large experience in thyroid surgery are agreed

If removal of one lobe is not sufficient to cure the patient a second operation may be performed upon the remaining lobe But this second operation should, in my opinion, never be a complete removal, as this involves too much risk of myxœdema or of tetany A considerable portion of the second lobe should always be left, together with one thyroid artery supplying it One sometimes hears it said that it does not matter if you do remove the whole gland, the patient can easily be fed upon thyroid, or grafting of thyroid may be done I venture to think that this is a grave mistake I believe firmly that total removal of the thyroid gland should never be performed for any disease whatever I am not disposed to make an exception even for malignant disease, although it is possible that there may be some very exceptional cases of this kind where it is not advisable to leave even a portion of one lobe But this matter I leave for discussion in my next lecture Not long ago I was consulted by a lady who had a small bilateral fibro cystic goitre of an extremely common type which was causing her no serious symptoms whatever To my extreme surprise I learnt that she had just been advised by a London consultant, who was not an operating surgeon, to undergo complete bilateral thyroidectomy on the ground that the gland might or would become cancerous! I need hardly say that no operation was done

The dangers of total removal—tetany and myxœdema—are well known Perhaps not so well known is the fact that there are persons who cannot take thyroid extract In any case, the condition of a person taking thyroid constantly is not so good as that of a person who has a bit of normal thyroid Even a small bit of natural gland is much better than none, for it can hypertrophy and gradually take on the functions of the gland Fortunately, it is a difficult matter to remove the whole thyroid gland completely, and many persons owe their lives, or at any rate their health, to the fact that an operator desiring and intending to remove the whole gland has accidentally left behind some outlying portion of it Of this, I described and figured an excellent illustration some years ago in my book on "Diseases of the Thyroid Gland"

Just as thyroid feeding cannot invariably be depended upon to take the place of a thyroid gland that has been removed, so is thyroid grafting an unsatisfactory and unreliable means of providing a patient with a due supply of thyroid Thyroid grafting is an operation by no means to be despised or condemned I have done it several times for cretinism, putting small pieces of gland either under the breast, in the subperitoneal tissue, or in the medullary cavity of the tibia Although in every case of mine the wounds have healed aseptically, the improvement in the patients' condition has not been sufficient to enable them to discontinue permanently the taking of thyroid by the mouth Of grafting after operations for removal of the thyroid I am glad to say that I have no personal experience, as none of my patients have ever needed it It is probable that when patients have been apparently restored to health by thyroid grafting, the improvement has been due rather to the development of some small portion of gland that was accidentally left behind than to the grafting At any rate, there is at present, so far as I know, no definite proof that thyroid grafting can be relied on to take the place of normal gland At present the operation, although often worth trying, cannot be said to have advanced beyond the experimental stage, and it is dangerous to rely upon its supposed efficacy For a full discussion of the whole subject of thyroid grafting, with many references to other papers, I must refer you to an interesting and valuable paper by Groves and Joll [11]

The Position as to Operation in Graves's Disease

In conclusion, Sir, I should like to express the opinion that exophthalmic goitre is a disease of which the treatment, whenever possible, should be carried out jointly by the physician and surgeon I venture to ask whether the time has not arrived when physicians should recognise that they can do little or nothing for its actual cure, but that they can do much to get the patients into a proper condition for operation On the other hand, the surgeon should realise the value of medical treatment as a preliminary to surgical interference, and should remember that there are stages of the disease during which the patient should be entirely in the physician's hands It is common to hear of patients, who might be much benefited by operation, being kept indefinitely under medical treatment in out-patient departments, or intermittently in the medical wards, before a surgeon is even asked to see them, and when he is called in it is often to some desperately bad case on which he is expected to operate immediately as a last resort

[illegible]

most other kinds of goitre, but that the dangers may, however, be greatly reduced by careful attention to details, especially in the selection of cases for operation, and in the choice of the time at which the operation should be performed, in the preliminary treatment of the patient, in the methods of operating and in the after treatment

That much benefit nearly always follows operation is undoubted, and that cure does sometimes follow as a direct result of the operation, especially in early and slight cases, there can be equally little doubt Even in really bad cases, in which operation must involve serious risk, so much improvement often results that operation should not be too lightly put aside

There is still much room for difference of opinion on many aspects of the question I have tried to put before you as fairly as I could both my own views and the views of those of larger experience than myself

In my next lecture I shall deal with varieties of thyroid disease other than Graves's disease I hope to be able to show you a number of patients upon whom I have operated both for this disease and for other kinds of thyroid tumour

---

PRINCIPLES OF PERCUSSION AND AUSCULTATION.[1]

BY FRIEDRICH MÜLLER, M.D., LL.D.,
PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF MUNICH.

THOSE who have taught physical diagnosis have realised, I am sure, the difficulty of giving precise definitions of the conceptions of the percussion sound and the auscultatory symptoms. The usual clinical terms "clear," "flat," "dead," "full" are metaphorical and not coincident with the conceptions of scientific physics. They therefore give rise to much confusion. We shall overcome these difficulties only if we go down to the very principles of physics and use the rules and terms of science instead of the ambiguous expressions of clinical practice. The works of Helmholtz, of Tyndall, and of Geigel[2] will give the best advice to all physicians who wish to deal more exactly with these problems of acoustics.

The varieties of sound are comprised in the following terms: 1. *Loud* and *soft* express the intensity or amplitude of the waves. 2. *High* and *low* or the pitch gives the number of waves in the second, and therefore the length of the single vibration. 3. *Long* and *short* mean the duration of the total sound. I propose not to use the term "timbre" or "colour" of sound, because this only depends on the combination of the fundamental tone with different overtones.

Difficulties will arise as soon as we proceed to analyse the sounds of percussion and auscultation, because the physical methods of analysing sounds have not been sufficiently worked out for our purpose. We were, therefore, obliged to find our own way. For the estimation of the intensity we have used a very thin rubber membrane armed with a minute mirror, which reflected a light ray on to a photographic film, or the microphone in combination with Einthoven's galvanometer.[3] The same instruments give evidence of the total duration of the percussion sound. A simpler method of estimation is based upon the physical law, that the intensity of sound diminishes with the square of the distance. This law is employed in otology for measuring the acuity of hearing. We can apply the converse principle and estimate the intensity of sound by the distance over which it is still perceptible. A flat percussion sound will be distinguished only in the immediate neighbourhood of the patient; a loud sound in the most remote seats of a large amphitheatre.

We conclude from our estimations that the percussion sound of the normal lung and other air-containing organs shows, not only a far greater intensity, but also a longer duration than the flat sound of a solid organ. The tracings with the sensitive membrane or the Einthoven galvanometer show for the full sound of the lung an amplitude three or four times as great and a duration twice (0·42 to 0·28 second) as long as the flat sound. It is obvious that such a comparison is only permissible if the same experimental conditions are kept—i.e., if the percussion stroke is of the same kind and intensity. But the conception of "dulness" ("matité" of Laënnec) is not fully identical with small amplitude and short duration. We realise that the problem is more complicated as soon as we proceed to consider the pitch.

In the first place we found great difficulty in analysing the pitch. The microphone proved to be unfit, because it was accompanied by too many errors and because it did not respond with the lower tones. The direct registration by sensitive membranes (rubber membranes or soap bubbles) and transmissions of its vibrations by a ray of light to a photographic film give beautiful drawings,[4] but it is often difficult to determine which part of the waves is dependent upon the fundamental tone of the membrane and which is the true expression of the given percussion sound. This method is not yet worked out perfectly, and it gives good results only if the sound is loud enough. We got the best results by the use of resonators. The spherical resonators of Helmholtz did not respond so clearly as those of conical form, to which Professor Röntgen has drawn my attention. The conical tubes were manufactured from tinplate. The length of the cone is four or five times as great as the diameter of the base. The apex of the cone shows a lumen of 2 millimetres and is applied directly to one ear, or by the tube of a binauricular stethoscope to both ears. The keynote of each cone is identical with that of a cylinder open at both ends—i.e., the conical resonator responds to a tone of double its wave length. We use a long series of such cones, the length of which varies from 10 centimetres to 3 metres. The application of such a long series of single resonators offers some inconvenience, and we therefore proceeded to use resonators of cylindrical shape. Two or more cylindrical tubes were fitted into one another, like a telescope; one end of the inner tube is closed and perforated by a small opening of 2 millimetres upon which the tube of a binauricular stethoscope can be fitted. The length, and therefore the keynote, of these cylindrical resonators can be changed easily, and their use has great advantages. A cylinder closed at one end responds to a tone of four time its wavelength. If the tube is applied with its open end to the chest wall for the purpose of auscultation, it follows the laws of cylinders closed at both ends and responds to a tone of twice its wave length—i.e., to the higher octave. The diameter of the tubes is of little importance. We use cylinders with a diameter of 3 or 5 centimetres. An experienced ear is easily able to distinguish with what length of the tube resonance takes place. The length of the tube expressed in centimetres permits one to read directly the pitch of the tone.

It is necessary to remember that the low fundamental tone of a resonator never can be evoked by a higher tone, but that a high tone is able to evoke the high partial tone of a big resonator. With the help of the resonator tubes we have been able to ascertain that the percussion sound of the normal lung is characterised by a very low note of the contra octave (especially A) or the upper half of the subcontra octave. Very often we found the best resonance with a length of the tube of 1·6 to 1·8 metres—that is, A_1 to G_1.

The foam-like substance of the normal lung answers with very low and slow vibrations to the stroke of the percussor, and we conclude that the fundamental tone of the normal lung is very low. But this very low sound is only heard if the lung is fully expanded with air and if the part set into vibration is great enough. The thinner edges of the base of the lung near the diaphragm or covering the heart give a higher pitch. The apex of the lung gives, too, a distinctly higher pitch than the lower parts, especially on the back below the scapula. The lung of a child gives a higher note than that of an adult; the emphysematous lung and the pneumothorax the lowest.

You may convince yourself of the resonant quality of the lungs by a very simple experiment. Put your hands on both sides of your own chest and sing the scale. You will feel no vibrations as long as you sing the upper parts of the scale. From a certain point of the scale vibrations of the chest wall become perceptible, and are strongest with the lower notes of the bass voice. My assistant, Dr. Edens, was able to record these vibrations of the chest wall with Otto Franks's sphygmograph, and has shown that the figure of thoracic vibrations exactly corresponds with the oscillations of the sungen tone. We may conclude that the lung is set into vibration like a Helmholtz resonator as soon as its fundamental tone is emitted. We understand why pectoral fremitus is commonly not distinctly perceptible on the female chest wall. The female lung has nearly the same low fundamental tone as the male, but the female voice is not suited to emit the low keynotes which only find resonance in the lung tissue.

The tympanitic percussion sound of the air-containing intestines is of distinctly higher pitch than that of the lungs; it responds to an open resonator of from 30 to 50 centimetres length—i.e., from D to E of the scale. The tympanitic sound is characterised by a simpler constitution.

---

[4] May und Lindemann · Graphische Studien uber den Percussionsschall, Deutsches Archiv fur Klinische Medizin, Band xciii., p. 100.

May and Lindemann have been able to trace its vibration by means of a soap membrane, and found that it nearly corresponded to a single tone, while the percussion sound of the normal lung gives a very complicated diagram made up of various higher, and especially lower, tones.

The dulness of the infiltrated lung (pneumonia) or pleuritic effusions shows not only a very small amplitude of the vibrations but also a deficiency of the lower tones. It is not only soft but higher too. And because the lower tones always have a longer duration than the higher ones, the percussion sound in case of dulness is quicker extinguished (damped) and has a shorter total duration than the sound of the normal lung.

Though the total duration of the percussion sound is always rather short, amounting only to half a second or less, the ears of many physicians are especially adapted to perceive the duration, and they therefore use the expression "short" instead of "dull," not without good reason. In beginning tuberculosis of the lung the percussion sound of the affected apex at first shows only the deficiency of the lower tones, and therefore appears *in toto* higher and shorter. A difference of amplitude (loudness) is scarcely or not at all perceptible in early cases; a distinctly smaller amplitude—i.e., real dulness or flatness—is a sign of more intense infiltration.

The physical analysis of the auscultatory phenomena presented greater difficulties than that of the percussion sound. The intensity of the respiratory sounds is so very small that our apparatus up to the present time proved unable to record its vibrations. Only the most sensitive of all acoustic apparatus, the human ear, is fit to perceive it fully. We first tried to use microphones and telephones of different types. But they did not respond to the sound of normal vesicular breathing, but only to that of bronchial and tracheal breathing. An exact exploration by the scale of tuning forks gave evidence that the telephone and microphone do not respond to low tones as well as to high ones, or to the lower tones not at all if they are of low amplitude. This experiment led to the conclusion that bronchial breathing was made up of high tones only, and that in vesicular breathing high tones are not present, but only low ones. An exploration by resonating tubes of different length proved that this assumption was right. Normal vesicular breathing gives only resonance with tubes of 120 to 300 centimetres length (C to A_1), bronchial breathing with tubes of 26 to 60 centimetres (F″ to D′). Consonating râles in infiltrated lung resonate on an average in the same part of the scale as bronchial breathing, partly with higher tones. The metallic sound in percussion as well as in auscultation (amphoric breathing, metallic resonant râles) are characterised by very high overtones perhaps of 1000 to 5000 waves in the second.

We must make the conception of bronchial breathing as clear as possible. Real bronchial breathing is heard over complete pneumonic infiltrations or over totally compressed atelectatic lungs—i.e., on the upper parts of pleuritic effusions. This characteristic breathing sound consists of only high tones, and resembles exactly the sharp *ch* sound of the German language. The so-called bronchial breathing over tuberculous cavities commonly shows a lower pitch. Tracheal breathing is not at all coincident with bronchial breathing, as is often said. The breath sound over the trachea shows especially the high pitch of a tube of the same diameter, but this sound is mixed with the low sound of vesicular breathing. *The bronchi which ramify into the interior of the lungs conduct the vesicular breathing sound to the trachea.* We can convince ourselves very easily of this fact if we practise the auscultation of the trachea with the help of a long rubber tube—viz., a gas tube averaging 2 metres in length. The long air tube between the trachea and the ear deadens or damps the high tones of the tracheal breathing nearly to complete extinction, and the low tones of the pre-existent vesicular breathing alone remain perceptible. This experiment proves that the interposition of an air space damps the higher waves more than the low ones, and a solid bar of wood or iron conducts the higher sound waves far better than an air tube of the same length.

The spongy substance of the normal lung seems to have a far more damping effect upon high sound, than air alone; it may be because the manifold reiteration of air bubbles and the walls of the lung vesicles give rise to reflection and extinction of the waves. A comparatively small layer of lung tissue deadens and extinguishes the high pitch of the underlying tracheal and bronchial tubes almost completely, and only in the immediate neighbourhood of the trachea and the principal bronchi are we able to hear a trace of its characteristic high breathing sound. In the lower parts of the lung no trace at all of the bronchial breathing sound is heard. The normal lung extinguishes, too, the sound of the heart over a short distance. Only if the lung is consolidated by inflammation, by neoformation of connective tissue, or by compression does its conducting power increase and equal the conducting power of solid masses, and under these conditions only are we able to perceive on the chest wall the high whistling sounds which originate in the bronchi. Characteristic bronchial breathing seems to originate only in the greater bronchi of the first, second, and third order. The smaller bronchi seem from our experiments to be too narrow to give origin to perceptible sounds.

It is not easy to give a convincing explanation of the origin of the normal vesicular breathing sound. It is likely that the stretching and successive extension of the lung tissue give origin to vibration of the lung substance as a whole and therefore to the low characteristic sound. A comparison between the size of the lung in the living body and the contracted organ after it has been removed at a necropsy shows clearly that the lung must be very greatly expanded in the normal thoracic cavity, and this expansion increases with every inspiration.

I have tried to give a picture of the results of our experiments in the following scale, and we may conclude from the scale that the normal lung responds on an average with the same low sound, if its fundamental tone is evoked by percussion or by the stretching of inspiration or by the voice. The fundamental tones of the cavities of the abdomen have a higher rate of vibration; the fundamental tone of the bronchi (bronchial breathing, consonant râles) takes its place between C′ and C″; and the metallic sound is characterised [illegible] The normal heart sounds and the [illegible] and therefore it is sometimes very difficult to distinguish systolic vesicular breathing from valvular murmurs.

Some physicians have tried to exaggerate the technical refinement of percussion and auscultation to artistic virtuosity, and to draw the keenest diagnostic conclusions from its application. I have tried to show that these methods of examination are not so much the object of artistic skill, but of scientific understanding, and that we first need a solid scientific foundation and criticism. A comparison between the [illegible] and auscultation with the results of [illegible] the necropsy finding often [illegible] very moderate in diagnostic conclusions from the physical examination, and that it does not grant so conclusive proof concerning the conditions of the inner organs as many of us have imagined.

THE BLOOD IN CANCER WITH BONE METASTASES.

By GORDON R. WARD, M.B., B.S.Lond., M.R.C.S. Eng.

In The Lancet of Feb. 8th there is an article on the above subject by Dr. A. W. Harrington and Dr. A. M. Kennedy. *In the course of this they refer to a somewhat similar case mentioned by myself in a communication to The Lancet,*[1] *which I should probably not have written* except under the stimulus of a previous case reported by Dr. Harrington and Professor J. H. Teacher. Like causes produce like effects, which is the reason for the following account of two, and perhaps three, more cases of the same nature which have since come under my observation. Two were under the care of the late Dr. Murrell in the Westminster Hospital and one under the care of Dr. Harry Campbell in the West End Hospital, to whom I am indebted for permission to refer to them. I am, unfortunately, unable to give nearly so detailed or valuable an account of these cases as Dr. Harrington has given of his, but the interest of the subject and the rather small number of cases on record appear to warrant mention of others. The cases are briefly as follows.

Case 1.—The patient was a woman aged 41 when first under observation about two years before her death. She was then suffering from "sciatica," and her previous history showed that she had had her breast amputated for malignant disease. The pain was found to be due to a pelvic tumour, and her subsequent history was one of slowly increasing tumour formation in connexion with the bones. For a while most trouble was caused by a tumour following fracture of the hip—this occurred about the time of the second blood examination. By the time of the third examination the lower end of the same femur was affected. At the time of the last count there were in addition pains in the shoulder and spine and girdle pains, arising no doubt from growth in the latter situation. These growths were verified by X ra For a while she had really very good health, but latter morphia in increasing doses was necessary. She was taki 5 grains daily at the time of the last count. Four examin tions of the blood were made in this case at intervals duri a period of two years. It will be noted that at no time w there a grade of anæmia at all comparable to that seen Addisonian anæmia, but that at the end signs of "bo marrow stimulation" began to appear. One may perha note here that the cases of Harrington and the last case he mentioned prove conclusively that the term "pernicio anæmia" often so confidently used after a blood examin tion corresponds to neither a pathological nor a clinic entity, and should be discarded as soon as possible. T results of the blood examinations are given in tabular for below with those of other cases.

Case 2—The patient, a woman, aged 44, was sufferi from marked curvature of the spine, shown by the X rays be due to a growth, and following amputation of the brea for epithelioma. Morphia was being given to the extent 24 grains daily for pain, but the progress of the diseas was comparatively slow. Only one blood examination w made.

Table showing the Results of Blood Examinations in Cases of Cancer with Bone Metastases.

—	Case 1.				Case 2.	Case 3.	Case 4.
Age	41.				44.	—	53.
Sex	Female.				Female.	Female.	Male.
Day of observation	1.	58.	300.	660.	1.	1.	1.

Spectrum	—	—	Oxy-hæmoglobin.	—	Oxy-hæmoglobin.	—	—

Case 3.—This is the case previously mentioned by me i The Lancet, and was that of a woman who had rapid r currence after amputation of the breast, and when examine had a large mass attached to the sternum, and no dou involving it, as well as two smaller nodules growing from th ribs. These masses did not involve the skin in any wa and those in connexion with the ribs were on the side of th body opposite to that from which the breast had bee removed. In none of the three cases at present mentione was there severe anæmia.

Case 4.—The patient was a man, aged 53. He was on under observation a few hours, being admitted in a dyin condition. Post mortem he was found to have a large carc noma of the stomach involving the whole circumference the stomach, the pancreas, omentum. and glands about th cœliac axis. There were no metastases in the liver, b some cirrhosis. There was advanced atheroma of the aor and a small aneurysm, as also thickening of the mitral an aortic valves. There was some perisplenitis, a few pleural adhesions, hæmorrhagic spots on the knees, and altered blood in the intestines. It would appear probable that the cause of death was the hæmorrhage into the bowel which must have taken place. The growth into the stomach was ulcerated, but there was no direct evidence that the blood, which was not in large amount, came from there. The bone marrow was examined in smears, but no cancer cells were found. There were a few white areas in the marrow seen with the naked eye, but these were due to localised leucoblastic reaction. Only the marrow of the sternum was examined, a small piece being trephined for the purpose.

---

[1] The Lancet, June 18th, 1910, p. 1688.

Sketch of small "giant cells" from the blood in Case 4.

There is thus no direct evidence of bone metastases in this case. The evidence for their existence is the difficulty of explaining the blood picture otherwise. It may well be argued that this evidence is very slight; that is admitted, but however that may be, the resemblance to other cases makes this one worthy of record. There was one rather remarkable point about this case, and that was the presence in the blood of many cells between 20μ and 30μ in diameter and apparently identical with the smaller giant cells seen in the marrow films after death. Except for the few megaloblasts and the very large number of normoblasts, the marrow was very like that of Addisonian anæmia. The one blood examination is subjoined.

In the first three cases there was obvious involvement of the marrow in metastases from primary cancerous growths. In all of these the blood picture was distinctly abnormal and similar in type, although in the first case the more marked abnormalities were of late occurrence only. The last case resembles very closely the case of Harrington and Kennedy, but there were no metastases in the small area of marrow examined. Until more cases have been collected useful comment is almost impossible, and these cases are therefore left without it. They may be of interest to those who, like myself, are keeping an eye on the literature of the subject and endeavouring to find fresh cases.

West Kensington

FATAL HÆMATEMESIS IN A CASE OF HEPATIC SYPHILIS.

BY DONALD E. CORE, M.D. VICT., M.R.C.P. LOND.,
PHYSICIAN, ANCOATS HOSPITAL, MANCHESTER.

THE patient, a young man, aged 29, a labourer, quite suddenly while at work vomited a large quantity of blood. He was taken to the central receiving house of the Manchester Royal Infirmary, and while he was there he again vomited blood He was sent to the infirmary at once, and when he arrived there he was found to have had another and very severe hæmatemesis in the ambulance. He was in a state of extreme collapse when he was seen at the infirmary—blanched, sweating, and pulseless, with shallow sighing respirations and a subnormal temperature. He himself was unable to give any account of his illness, but his mother, who was with him, stated that he had been under treatment at the Royal Infirmary some two years previously for vomiting of blood. She also said that there had been no history of any digestive disturbance at all, at that time or since. She was very emphatic on this point, as stress had been *laid on this absence of gastro-intestinal* disorder at the time of his first bleeding. From her account he had lived an exceptionally steady healthy life, and had never had any illnesses at all with the exception of these attacks of hæmatemesis.

The patient continued to bring up blood in the accident room, and was sent up to the ward at once, any examination being out of the question. He was transfused as soon as he reached the ward, and revived sufficiently to enable the pulsations in the radial artery to be felt. This improvement was immediately followed by a severe attack of bleeding, necessitating further transfusion. He then definitely improved, and complained of severe epigastric pain, more or less diffused over the whole of this region. He was given some morphia and went to sleep. He remained in this condition for some eight hours, when he suddenly became restless, and the shallow respirations returned. The pulse at the wrist failed almost immediately, and the patient died a few minutes after the onset of these symptoms. There was no appearance of any blood externally, and it was supposed that he had had a severe internal bleeding.

A post-mortem examination was performed on the day after death by Dr. W. B. Anderton.

Necropsy—The body was that of a muscular, well-developed young man, the skin and mucous membranes showing marked pallor. Fat was present in the subcutaneous tissues in fair amount There was no

d and weighed
rdium was pale
es of subendo-
over its septal
There was no
ventricle were
ry valves were

The right and left pleuræ were normal. The right lung weighed 21¼ oz., collapsed well, and showed moderate pigmentation. It was spongy and crepitant throughout, moderately congested, and exuded a small quantity of frothy serous fluid on compression The left lung weighed 17 oz., and presented the same appearances. The air passages were normal.

Alimentary canal. There were no signs of varices or ulceration in the walls of these viscera. A fairly large amount of blood occupied the *lumen of the large intestine and of the lower half of the small intestine.* There was no undue distension of the bowels and no sign of blood in the stomach contents. The pancreas was normal The omentum showed the presence of fat in normal quantity. The peritoneum was dry but otherwise normal.

were normal.

substance of the liver up into large areas of liver tissue of a homogeneous. pale brownish-yellow colour. The anterior part of this lobe was, however, of a still paler colour, presenting a fine mottling on section

to be fairly normal. There was no
h thickening and opacity of the
arable adhesions to the diaphragm.
as finely granular, especially in the
right lobe.

of hepatic syphilis, where the disease resembles ordinary cirrhosis of the liver. The symptoms are usually those of pain in the right hypochondrium, with more or less gastric disturbances, occasional hæmatemesis, and ascites. Jaundice is rare in these cases of hepatic cirrhosis, and according to Hale White so also is ascites. On examination of the abdomen the liver and spleen are found to be enlarged and firm. Pain generally is a prominent symptom, owing to the *perihepatitis and perisplenitis,* and although in the case recorded above there appears to have been a remarkable absence of this symptom, yet from the appearance post mortem of the liver and spleen, which were unduly adherent to the diaphragm, some pain almost certainly must have been present at one time or another.

The diagnosis of these cases rests on the preponderance of syphilis over alcohol in the history, and the relief of symptoms by antisyphilitic treatment. Rolleston has pointed out that the *routine treatment of ordinary alcoholic cirrhosis* consists of potassium iodide, and that cases recorded of cure in this disease are, in all probability, cases of syphilis of the liver.

Two further points of interest in the above case are, Sanatorium draws its patients from all parts of the United Kingdom, and it is only possible to keep in touch with them by means of the post. An annual census is taken, but, with every possible care, the annual returns are incomplete. Municipal dispensaries, which supply the needs of a definite area, should experience considerably less difficulty in tracing the after-histories of their patients.

Immediate results of treatment.—I should perhaps refer to immediate results. As evidence of the usefulness of any method of treatment, records of the immediate benefit received by consumptives, given in terms of "Improved," "Much improved," &c., are not of any great value. In practice, the presence or absence of tubercle bacilli and the amount of exercise a patient can take are the most useful points on which to have information. In sanatoriums it is but rarely that a patient, even if far advanced, fails to improve; indeed, a method of treatment which fails to benefit, even if only temporarily, the very large majority of cases treated by it needs no further investigation. Thus it is that statistics of immediate results have but small significance compared with similar records of ultimate results.

Records of the King Edward VII. Sanatorium.

The data reviewed in this paper consist of the records of 1082 patients who were discharged during the period July 1st, 1907, to July 1st, 1911. (I have omitted the year 1906-07, as during a part of this, the first, year the work of the Sanatorium was not completely organised.) The after-histories of these 1082 patients, then, cover a period ranging from a maximum of 5 years and 4 months to a minimum of 16 months subsequent to their discharge from the Sanatorium—a long enough period to give the returns a distinct value.

Diagnosis.—These 1082 patients were sent by medical practitioners as definite cases of pulmonary tuberculosis. The diagnosis was not confirmed by ourselves in 52 cases, or 4·8 per cent. of the total admissions; in fact, to be more explicit, we definitely excluded pulmonary tuberculosis in 52 cases. These cases are, of course, excluded from our annual returns. The after-histories of these 52 patients favour the correctness of our opinion. Not one of them as yet has shown any sign or symptom of pulmonary tuberculosis. There have been three deaths—from malignant disease of mediastinum, cancer of larynx, and appendicitis respectively. That nearly 5 per cent. of patients sent in as pulmonary tuberculosis were not suffering from the disease is evidence of the difficulty of diagnosis. It is proof that the practitioner sometimes errs on the side of safety, and proof also that those are justified, who are sceptical of a positive diagnosis on paper, in the absence of tubercle bacilli. It would be interesting to know the experience of dispensaries on this point.

The next feature of interest concerning diagnosis is, that of the 1030 cases in which the diagnosis was confirmed by ourselves we found the tubercle bacillus in 82 4 per cent., leaving 17·5 per cent. of cases in whom the positive diagnosis was not thus confirmed. Compared with dispensary work, I imagine the figure of 82·4 per cent. of cases with tubercle bacilli is a high one—e.g., in THE LANCET of Oct. 5th, 1912, Dr. James Fairley states that of 244 cases of pulmonary tuberculosis at that date attending the dispensary at Portsmouth, tubercle bacilli had been found in 39·4 per cent. only. I should add that the sputum examinations at the Sanatorium are made with great care.

Our data, then, consist of 1030 cases diagnosed as pulmonary tuberculosis, of which 82·4 per cent. had tubercle bacilli in the sputum and 17·5 per cent. had no tubercle bacilli so far as we could determine. Of this number, 110 have been lost sight of (a good many of these have been traced up to last year), and the remaining 920 have been traced up to the present date. To simplify matters, I shall not take into account these 110 patients who have been lost sight of, but deal only with the 920 whose after-histories are complete. This total of 920 patients is divided into two main classes—(1) those in whom tubercle bacilli were found, 764 in number; and (2) those in whom tubercle bacilli were not found, 156 in number

Considering first the 764 cases in whom tubercle bacilli were found: Of this number, 57·1 per cent. are known to be well or alive, and 42·8 per cent. are known to be dead. If we divide these 764 cases into the customary three groups, I., Early, II., Moderately advanced, III., Advanced, the following is the result. Of 183 cases in Group I., 153 (83·6 per cent.) are well or alive; 30 (16·3 per cent.) are dead. Of 357 cases in Group II., 220 (61·6 per cent.) are well or alive; 137 (38·3 per cent.) are dead. Of 224 cases in Group III., 64 (28·5 per cent.) are well or alive; 160 (71·4 per cent.) are dead.

The records of the cases in whom no tubercle bacilli were found are very different reading. Of the 156 in this group, 89·1 per cent. are well or alive, and 10·9 per cent. are dead. Two of the deaths were due to tuberculous meningitis. Of these 156 patients, 18 per cent. have, since their discharge, again shown symptoms of pulmonary tuberculosis.

To summarise these records of the 920 patients: Their condition at the present time, after a lapse of from a minimum of 1 year and 4 months to a maximum of 5 years and 4 months, since discharge, is as follows: (*a*) Those in whom no tubercle bacilli were found (156), 89·1 per cent. are well or alive, and 10·9 per cent. are dead. (*b*) Those in whom tubercle bacilli were found (764), Group I. (183), 83·6 per cent. are well or alive, and 16·3 per cent. are dead. Group II (357), 61·6 per cent. are well or alive, and 38·3 per cent are dead. Group III. (224), 28·5 per cent. are well or alive, and 71·4 per cent. are dead. Such are the bald facts. They represent the degree of success which has attended the work of the Sanatorium up to July, 1911, as judged by the only reliable test—the test of time.

To comment briefly on these data: The very favourable results obtained in the patients without tubercle bacilli is noticeable. The exact significance of the figures depends on our attitude towards patients without tubercle bacilli. Are we justified in holding that these cases have been rescued from tuberculosis by the treatment they received, or is it that a large number of them were no worse than many who receive no treatment at all and get well? That they all had evidence of pulmonary tuberculosis I had no doubt, nor had my colleagues, but I must confess to an inability to differentiate with any certainty in many instances between a recent and quiescent focus of disease and a lesion that is probably obsolete and of no clinical significance. It is only natural, perhaps, that I should lean to the view that a considerable number of these patients have been cured of incipient disease. It is clear, however, that, granted the correctness of the diagnosis, this class of case is very amenable to cure, and does not furnish at all a severe test to any therapeutic measure.

But when we come to consider the 764 patients, all of whom had tubercle bacilli, we are on surer ground. There can be no possible doubt as to the existence of the disease. The records of the 183 early cases (Group I.) with tubercle bacilli present, showing 16·3 per cent. of deaths and 83·6 per cent. well or alive, compare very favourably indeed with the records of the class just considered, in which no tubercle bacilli were ever found. The difference amounts only to some 5 per cent. more deaths and some 5 per cent. fewer "Well or alive." The physical signs and symptoms were very similar in both sets of patients. Other things being equal, then, the presence of tubercle bacilli has a somewhat unfavourable significance. None the less, the average patient with early disease and with tubercle bacilli present does well under sanatorium treatment. Many cases of this nature doubtless get well without anything more active in the way of treatment than their removal from an unfavourable environment, a method of cure which sanatoriums accomplish very effectually. There can be no doubt, too, as to the value to the patients of the practical lessons in hygienic living as taught in well-managed sanatoriums. Education and cure go hand in hand.

Group III., including 224 cases of markedly advanced disease, calls for little or no comment, except perhaps on the score that these advanced cases continue to form a considerable proportion of admissions to sanatoriums. 28·5 per cent. well or alive after some years represents a measure of success, some prolongation of life and a few apparently complete recoveries, but the mortality of 71·4 per cent. shows how little permanent benefit is to be expected from sanatoriums in this class of case.

I have left Group II. to the last, as being the most interesting. The type of case falling into this group is the one most commonly met with. No longer a case of early and very limited disease, a patient of this kind, with perhaps two or three lobes affected, usually still retains unimpaired his general condition and recuperative power. If only the onward march of the lung disease can be stayed and *arrested, complete restoration to health and capacity for* work is still to be looked for with confidence. Failing efficient arrest, the lapse into a hopeless condition is inevitable.

It is this type of pronounced, but still recoverable, disease that provides the best test for any method of treatment. The bacillus-free case and the very early case even with tubercle bacilli present may get well without any treatment, and probably often does so. Spontaneous cure, however, in a patient in whom the disease has obtained a good hold cannot be common. Sanatorium treatment alone, as shown by our *figures, does not do all we could wish for in these cases.* A mortality of 38 per cent. in so short a period as 1¼ years to 5¼ years is unpleasantly high, even if 61 per cent. well or alive after a like interval gives us some substantial measure of encouragement. To judge by other after-histories which I have followed up for ten years or more, we may expect a mortality of some 50 per cent. in this group at the end of seven years, subsequent to discharge, after which the rate of mortality should drop considerably. It is this type, the type which represents the average consumptive, that requires something more than sanatoriums can give.

The Significance of the Disappearance of Tubercle Bacilli from the Sputum.

There is nothing fresh in the observation that patients who lose their tubercle bacilli as the result of treatment have a more favourable outlook than those who, though immensely improved, do not lose them. None the less, the results of our observations on this particular point are more striking than we had expected. Of the 764 patients who on admission to the Sanatorium had tubercle bacilli in their sputum, 158 only, or 20·6 per cent., lost them before discharge. The small proportion of patients who lose their tubercle bacilli after an average of some four months' sanatorium treatment is significant. It means that but few, apart from the very early cases, can hope to leave a sanatorium apparently cured. It is to the patient's interest that he knows this. What it means to the consumptive to lose his bacilli is shown by the after-histories of the 158 patients who were fortunate enough to do so. Of 158 patients who lost their tubercle bacilli before discharge, 84·1 per cent. are well or alive and 15·8 per cent. are dead. As a comparison the following are the after-history records of the remaining 606 patients who did not lose their bacilli Of 606 patients discharged with tubercle bacilli still present, 50·1 per cent. are well or alive and 49·8 per cent. are dead. It is very encouraging also to note that the patients with well-marked disease (included in Group II.) who lose their tubercle bacilli have quite as good a prognosis as the slight cases (Group I.) who lose their bacilli. Our records in this respect are as follows. Of 79 cases in Group I. who lost their tubercle bacilli, 87·3 per cent. are well or alive, and of 64 cases in Group II. who *lost their bacilli no less than* 90·6 per cent are well or alive. Only a few cases of very advanced disease lost their tubercle bacilli, but of these, 15 in number, 40 per cent. are in fair or good health at the present time.

The disappearance of tubercle bacilli from the sputum is, then, a factor of the highest importance from the point of view of individual prognosis, and in the interest of the public health the advantage of having sputum cleared of bacilli is clearly no less great. In the treatment of pulmonary tuberculosis this should be our aim. We should be satisfied with nothing less. Further, to judge by our results, we have, in the persistence of, or in the disappearance of, tubercle bacilli, evidence of the greatest significance as to the value of any method of treatment.

In *the opinion of* some physicians, notably Löwenstein, Bandelier and Roepke, and Curschmann, the combination of sanatorium treatment with tuberculin treatment is very much more effective in clearing the sputum of tubercle bacilli than sanatorium treatment alone. This statement, coming as it does from experienced observers, carries considerable weight, and in itself calls for a thorough and systematic trial of tuberculin in sanatoriums. The confirmation of these observations is clearly a matter of the very highest importance.

Conclusions.

In making this survey I have tended perhaps somewhat to belittle the value of sanatoriums, in that I have dwelt more upon what they fail to do than on what they actually accomplish. My object has been to indicate in what *directions we may look for material improvement in the* future, as compared with the past, if tuberculin is indeed a potent additional factor for good.

What we hope to find in the near future is that a higher proportion of patients is being discharged free of tubercle bacilli, and later on that the mortality year by year is sensibly falling. Our record for "T.B. not found" cases of 89·1 per cent. well or alive after some years cannot be very much improved upon, but the record for early cases of 83·6 per cent. well or alive gives some scope for improvement. However, it is the results obtained in the treatment *of the somewhat more advanced cases, the big class classified* in Group II. by most sanatorium physicians, to which we should chiefly look for the information we are seeking as to the value of tuberculin.

There is one other point which is pertinent to my subject. Supposing that dispensaries prove the truth of the contention, that with the aid of tuberculin early cases of pulmonary tuberculosis can be as certainly benefited in their own homes or whilst at their work, as by sanatorium treatment, sanatoriums will have seriously to consider the advisability of refusing to admit the very cases which, at present, they *endeavour to admit to the exclusion of all others* This sounds very revolutionary. Still, it is logical enough, granted the truth of the premises. Sanatoriums could then concentrate upon the less favourable cases, for whom, as I have previously noted, something more is required—longer treatment certainly.

An increasing number of dispensaries will ere long be contributing their quota of evidence on this very important subject. It is earnestly to be hoped that the records of these institutions will be kept and published upon some common basis, that particular note be made as to the presence or *absence of* tubercle bacilli in the cases of pulmonary tuberculosis treated, and that every effort be made systematically to obtain after-histories. The value of tuberculin as an addition to sanatorium treatment is a question which falls to the lot of the King Edward VII. Sanatorium and similar institutions. Our answer is now in the making.

Appendix.

I add as an appendix detailed records of the patients dealt with, set out in the German method, showing all the after-history results in successive years. For the classifying of ultimate results the German method is the only one which is entirely satisfactory.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ANEURYSM OF THE DESCENDING THORACIC AORTA PRESENTING SOME UNUSUAL FEATURES.

BY REES PHILLIPS, M.D., B.S. LOND.,
ASSISTANT MEDICAL OFFICER, LAMBETH INFIRMARY.

THE points of interest in this case appear to be: (1) The absence of manifest physical signs during a long course of severe symptoms (it was only in the last few weeks of life that a diagnosis was established); and (2) the unusual direction that the aneurysmal sac took—into the base of the *right* chest.

The patient, a male aged 43 years, was first admitted to Lambeth Infirmary in July, 1911, complaining of periodic attacks of pain resembling right renal colic. There was a history of similar attacks for two years previously. Physical examination and examination of the urine were negative. He remained in the infirmary a week, and went out "improved", but the nature of his pains was undetermined.

The patient returned to the infirmary on Jan. 31st, 1912, and remained until Feb. 15th. He had several attacks of apparently agonising pain radiating from the right hypochondrium to the right groin while in the infirmary, but again a careful examination of chest, abdomen, and urine failed to throw light on the condition. There were no signs of locomotor ataxy, and no history of syphilis was elicited.

On May 21st the patient came to the infirmary again, and remained until July 18th. His symptoms were as before, but his general appearance had deteriorated. His skin was getting pigmented, almost suggesting Addison's disease. It was now noticed that the apex beat of the heart was a little outside the usual position, and there was a heaving impulse around the nipple. A faint systolic mitral bruit was heard.

On July 23rd the patient was again admitted to the infirmary with similar symptoms and he remained until August 29th. On admission it was noticed that his right kidney appeared palpable. The urine was normal. On July 25th he developed signs and symptoms of right basal pleurisy with some blood-stained expectoration. It was noticed that he was getting sallower, with general loss of muscular tone. The systolic blood pressure on July 27th was 130 mm. Hg. The symptoms improved and the patient was discharged on August 29th, but with some dulness at the right base.

The patient was finally admitted on Nov. 7th, 1912. His general condition appeared worse. He was sallow, flabby, and rather wasted. There was still some dulness, with deficient breath sound at the right base, and the heart apex beat was outside the normal position, but otherwise nothing was made out to account for the severe pains that he still suffered periodically. I heard that he had been in Middlesex Hospital in the March previous, and Dr. K. D. Marriner, the medical registrar, kindly informed me that a positive Wassermann reaction had been given, and that the case had been treated for specific myocarditis. The patient continued to suffer great pain in the loin, but no change was observed in the physical signs until December, when a heaving pulsation was noticed at the right base. It was obviously an aneurysm, either of the aorta or of the right renal artery. No pulsation was felt in the abdomen.

Laparotomy was performed on Dec. 17th by Mr. Wilfred Trotter, and the condition was found to be an aneurysm of the thoracic aorta bulging the diaphragm downwards and extending behind the liver. The aneurysm increased rapidly in size and formed a striking pulsating swelling in the right base. The patient became gradually weaker and died on Jan. 10th, 1913.

Post mortem a limited examination was made. The heart was apparently healthy, not enlarged, but displaced. The right pleural cavity contained much clear sero-sanguineous fluid, and there were extensive fine adhesions between the right lung and the pleura. The whole extent of the aorta showed diseased intima, which was extensively marked with brittle plaques. An enormous saccular aneurysm proceeded from the back of the lower part of the thoracic aorta to occupy the whole of the right base. The neck of the sac admitted the closed fist and the margin was bounded by a calcareous ring. The lower four dorsal vertebræ were extensively eroded, as were the last two ribs. The œsophagus, lying in front of the aorta, was apparently unaffected.

I am indebted to Dr. A. Lionel Baly, our medical superintendent, for permission to publish this case, and I also wish to thank Mr. Trotter for his courtesy and kind services in connexion therewith.

Lambeth Infirmary, Brook-street, Kennington-road, S.E.

TWO CASES OF FRONTAL SINUSITIS WITH BONE COMPLICATIONS.

BY W. S. KERR, M.B. EDIN., F.R.C.S. EDIN.,
SURGEON, EAR AND THROAT DEPARTMENT, ROYAL INFIRMARY, SHEFFIELD.

I PUBLISH these cases to show the varying conditions of bone complications one may meet with in this condition.

CASE 1.—I was consulted in January, 1911, by a girl, aged 19, who complained of very severe pain over the left eye and headaches of two weeks' duration. She had been troubled with nasal catarrh for many years, and had had adenoids removed nine weeks previously. There was no pus to be seen in the nose and an attempt to catheterise the sinus failed. Her temperature was 100° F. Palliative measures failing to give relief, I opened the sinus on Jan. 28th. The mucous membrane was much swollen and intensely congested. No pus was present, but much mucus secretion was evacuated. The temperature soon fell to normal and the pain disappeared. The tube was removed two days later, and the patient remained well for five days. On Feb. 5th she suddenly complained of severe frontal and occipital pain accompanied by retching and vomiting. Her features became swollen and puffy and her temperature ran up to 104°. The pain was especially marked over the left vertex, where there was intense tenderness with slight bogginess. The frontal wound remained healed and clean, and there was no suggestion of an erysipelatous infection. The sinus was reopened and freely drained. Pus was still absent. That evening the temperature rose to 105.4°, although the headache was somewhat relieved. The retching continued, and the patient remained seriously ill. Some cerebro-spinal fluid drawn off by lumbar puncture was kindly examined by my colleague, Dr. A. E. Barnes, and found to be normal. This condition of the fluid, together with the absence of increased pressure in the cerebro-spinal sac, made it improbable that the symptoms were due to any intracranial complication. A blood count showed 21,500 white cells. The temperature gradually fell and the other symptoms abated. Pus began to drain freely from the wound and on the 14th the temperature was normal. She remained well until February, 1912, when, owing to a recurrence of the frontal pain and headache, a radical operation was performed on the left frontal sinus and ethmoidal cells, which resulted in complete recovery.

CASE 2.—This case was that of a man, aged 42, who complained of pain and swelling over the right side of the forehead of eight weeks' duration. When I first saw him, in November, 1912, the swelling was circumscribed, fixed and firm, with no bogginess or implication of the skin. There was no pus to be seen in the nose, but there was marked nasal obstruction caused by hypertrophy of the turbinals and a large left septal ridge and spur. The swelling eventually showed signs of fluctuation, and pus, infected with bacillus pyocyaneus, was evacuated. On Nov. 25th I did a radical operation on the right frontal sinus. There was a large bony erosion of the anterior wall and a smaller one on the floor of the sinus. The sinus was filled with pus. The remainder of the anterior wall, which was carious, and the floor were removed, and the anterior ethmoidal cells, which were also suppurating, were eviscerated. The man made an uneventful recovery.

The alarming symptoms in the first case were undoubtedly due to the premature withdrawal of the drainage-tube, and the bogginess and intense pain over the left side of the vertex pointed to a commencing infection of the bone. The rapid disappearance of the symptoms on the re-establishment of free drainage was the most marked and satisfactory feature of the case. The swelling in the second case was at first so firm, circumscribed, and comparatively painless that it suggested either a gumma or sarcoma rather than a simple inflammatory swelling.

Sheffield.

NOTE ON A CASE OF A LARGE CONCRETION COMPOSED MAINLY OF CALCIUM PHOSPHATE FOUND INSIDE THE FISTULOUS CHANNEL IN A CASE OF FISTULA IN ANO.

By D. W. Keiller Moody, M.D., C.M. Aberd.

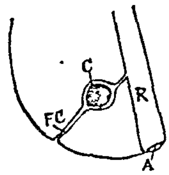
Is the following case unique?

A man aged 62 years was admitted to Addenbrooke's Hospital, Cambridge, under the care of Mr. Joseph Griffiths, suffering from a fistula in ano. He had never had any pain or discomfort, and he only sought medical advice because he said he noticed on going to stool a little "matter," and wondered if there was anything wrong. After dilating the sphincter an incision was made over the fistula and passing through the sphincter. The knife struck a hard object, which turned out to be a concretion about the size of a schoolboy's marble; it was very hard and fairly uniform in shape. It was found in the fistulous channel, not projecting into the rectum, but close to the rectal opening.

Fig. 1.

From a photograph of the concretion.

Fig. 2.



Diagrammatic sketch to indicate site of concretion. F C, Fistulous channel. C, Concretion. R, Rectum. A, Anus.

One thought it might be a gall-stone, a pancreatic, prostatic, or salivary calculus, or foreign body swallowed, or some insoluble drug taken over a long period. But it turned out to be essentially a phosphate of lime concretion.

Dr. F. G. Hopkins, F.R.S., of Cambridge University Physiological Laboratory, very kindly analysed it. It was found to contain: calcium phosphate, 88 per cent.; magnesium phosphate, 2·5 per cent.; stercobilin and altered bile pigments, 5 per cent. (circa); dried mucus and other organic matter, 2 per cent.; salts other than phosphates, and traces of undetermined substances, 2·5 per cent.

I have asked many surgeons as to how it got there. Most of them "gave it up"; but one said he thought it probably got lodged in a diverticulum and, increasing in size as years went on, it eventually ulcerated its way through and so produced the fistula. This seems quite a reasonable view.

Royal Sanitary Institute.—A sessional meeting of the institute will be held at 90, Buckingham Palace-road, on Tuesday, March 11th, at 7.30 p.m., when a discussion will take place on Milk and Dairies Bill, to be opened by Mr. Herbert Jones, medical officer of health, Herefordshire combined districts. Among those who expect to take part in the discussion are Dr. A. G. R. Cameron, Mr. F. E. Fremantle, Mr. Hugh Stott, Dr. J. S. Tew, and Mr. J. Tubb-Thomas. General discussion is invited. The chair will be taken by Mr. A. Wynter Blyth. Tickets for admission of visitors may be had on application.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Demonstration of Cases.—Summer Diarrhœa and Summer Heat.

A meeting of this section was held on Feb. 28th, Mr. A. H. Tubby, the President, being in the chair.

Dr. F. Parkes Weber showed a case of Slight Congenital Deformity of the Hands in a Child. The deformity consisted in partial flexion of the fingers at the metacarpophalangeal joints. The child could use his hand fairly well to grasp with, but could not completely extend any of the fingers except the left index finger. Both the little fingers could, however, be *passively* completely extended. In some spontaneous positions of the hands slight ulnar deflexion of the fingers was likewise noticeable. The patient, a boy, aged 17 months, was born at full term, easily, without instrumental help. He was the only child of healthy parents, who were both young. The mother had had one miscarriage before the child was born. There was no history of any similar deformity in the family, nor was there any special family tendency to arthritic affections. The child had a little convergent squint, and possibly slight hydrocephalus. He likewise presented some rachitic "beading" of the ribs, but otherwise appeared well developed and mentally normal. The position of the hands at first suggested the carpopedal contractions in tetany, but the child had no facial irritability, and nothing else which would in the slightest degree suggest tetany. The feet and toes were quite normal in shape and position. Since the child was two months old the mother had practised a kind of massage with passive movements for his hands, and thought that he could use his fingers better as a result of her treatment. Skiagrams of the hands showed nothing special. There seemed to be no disease in the joints. Dr. Weber had not heard of any exactly similar case. The fault seemed to lie chiefly in the muscles which extended the first phalanges.—In the discussion which followed, the President expressed the opinion that the condition was due to congenital tightness of the palmar fascia.

Dr. Weber also showed a case of Infantilism due to Mitral Stenosis. The patient, a girl aged 15, had the stature and appearance of a girl of 10.

Dr. F. G Crookshank showed a case of a Mongoloid child. The boy was a mongoloid of undoubted European parentage, in whom ethnic characters, conforming to a type of racial mongolism, were well marked without the coincidence of any trace of rickets, tuberculosis, syphilis, dysthyroidism, or other disturbing factor. There was no coarse bodily or mental defect, and such features as the fissured tongue and the orangoid ear, so common in mongoloids of the lower grades, were absent. But some traits were present that were simian or orangoid. The child, aged 5 years, was the younger of two sons born to a father who was aged 38 years and a mother who was aged 28 years. The elder brother, aged 7 years, was thin and nervous. The patient himself had a yellow skin and dark hair, though his mother stated that at birth he was "almost black." His hair was fine; his eye-focus of a characteristic form (though the eyes were not "oblique") and his profile was distinctly Chinese. The head, as in a certain proportion of mongoloids, especially of higher grade, was well developed occipitally. The lips were extraordinarily plastic, and the boy, when in the mood, would project them in trumpet form and hoot in imitation of a motor-car, producing noises precisely like those emitted by anthropoid apes. In both jaws the canine teeth were markedly long and tusk-like. The lower incisors were small and the lateral incisors in the upper jaw were notably smaller than those which were central. The testicles were small and probably descended late. He had what had been called a "high pelvis," the crests of the ilia appearing to rise high in the loins, so that the folds of the groins included a more acute angle than usual. He was highly estimated by his comrades as a contortionist.

Dr. **EDMUND CAUTLEY** showed a case of Mongolism in a baby 3 months old.

Mr. J. E. **ADAMS** showed two cases of Congenital *Coalescence of Radius and Ulna*. They were of two children in the same family in whom deformity had been noticed from birth. Both forearms were held in a position of pronation, and although there was movement at the inferior radio-ulnar articulation, supination was almost absent. There was a forward and outward curve in the shaft of the radius. Skiagraphy had shown that the radius was fused with the ulna a short distance below its head, and the deformity was the same in both forearms and in both children. By the kindness of Mr. S. G. Shattock he was enabled to show a specimen from the museum of St. Thomas's Hospital which illustrated precisely the same deformity. A similar case had been described by Dawson.[1] Suggestions were invited as to treatment.—The **PRESIDENT** and Mr. E. **LAMING EVANS**, speaking from observation on a similar case, advised against operative measures.

Mr. **DOUGLAS DREW** showed: 1. A case of Lymphangioma of the Axilla. The patient, a baby aged 9 months, was admitted to the Queen's Hospital with a large, soft, lobulated tumour of the axilla. The tumour occupied the whole axillary space extending up to the clavicle, and required an extensive dissection for its removal, as it surrounded the vessels and nerves. In order to facilitate this the pectoralis minor was removed with the tumour. The specimen was a good example of this variety of tumour. 2. A case of Cicatricial Contraction of the Thumb following a Burn about 18 months previously. X ray photographs showed the thumb drawn back and bound down to the wrist by dense fibrous tissue. After dividing the contracted tissue and liberating the thumb the raw surface was covered by a large flap cut from the back of the hand. 3. A case of Separated *Epiphysis of the Femur treated by Plating*. The operation was performed on Dec. 9th, 1909. The child had been temporarily lost sight of, and was exhibited because the plate had not been removed. An X ray photograph showed that in the process of growth the screw in the epiphysis had been gradually drawn out; there was no shortening of the limb, and the movements were free. As the plate caused no inconvenience and was not hindering growth it did not appear necessary to remove it.

Mr. **EDRED M. CORNER** showed a case of Costo-transversectomy: Spinal Caries and Mediastinal Abscess. The patient, a male aged 6 years and 5 months, was admitted on Dec. 6th, 1909, to the Hospital for Sick Children. On admission there was some kyphosis in the lower dorsal vertebræ, with indications of abscess formation on the left side at the level of the eighth dorsal vertebra. A radiogram (Nov. 30th) showed the existence of a large mediastinal abscess in front of the lower dorsal vertebræ. The operation of costo-transversectomy was done on Dec. 14th, the abscess being opened and drained on the left of the spinal column at the level of the eighth dorsal vertebra. A radiogram (Dec. 29th) showed the abscess cavity and some destruction of the ninth and tenth dorsal vertebræ, especially in the transverse processes of the left side and in the heads of the corresponding ribs. By two operations, on Feb. 18th and March 16th, 1910, the abscess cavity was scraped. On May 17th the heads of the ninth and tenth ribs on the left side were excised. A radiogram (July 8th) showed no indication of abscess cavity remaining; there was formation of new bone in the damaged ribs. On Nov. 22nd a sinus was scraped. On Feb. 28th, 1911, the patient was sent to a convalescent home in a Phelps's box, still having a small sinus. He was readmitted on Oct. 1st, 1912. On Oct. 3rd an emulsion of bismuth and iodoform was injected into the sinus. A radiogram showed a small cavity containing bismuth and considerable destruction in the lower dorsal vertebræ, especially the eighth, ninth, and tenth. The sinus gradually closed after the injection. When exhibited the patient had a marked but not extreme degree of kyphosis in the lower dorsal region. On the left of the spine at the level of the ninth dorsal vertebra, there was a depression marking the position of the old sinus, which had healed. A radiogram (Feb. 10th) showed no abscess formation, but there was destruction of the bodies of the lower dorsal vertebræ, especially the ninth and tenth.

Mr. **CORNER** also showed a case of Congenital Absence of Fibula, Deformity of Tarsus, and Absence of Toe. The patient was a baby and presented the appearance characteristic of the condition. A skiagram showed the absence of the fibula. The tibia was bowed sharply and seemed shorter than the other. The summit of the convexity of the tibia was sharp and presented a groove or dimple over it. The movements of the ankle-joint were somewhat restricted. Apparently the fifth toe was absent. The doctor who first saw the patient diagnosed an intra-uterine fracture which had united. The absence of the toe led to the correct diagnosis, confirmed by the skiagram, of "congenital deformity of leg." In addition the skiagram demonstrated the characters of the deformity; absence of fibula, one centre of ossification representing both the astragalus and calcaneum, absence of the fifth toe and its metacarpal.

Dr. **CAUTLEY** showed a case of Chronic Albuminuria with Hepatic Enlargement. The girl, aged 8 years and 2 months, was the daughter of healthy parents, but a grand-parent and great grandparent were said to have died from phthisis. She had had measles, varicella, mumps, and pertussis. During 1910 she was an in-patient at another hospital for four months for albuminuria. Later on a gland was excised from the left side of the neck, and tonsils and adenoids were removed. From June 20th to July 8th, 1911, she was admitted to the Belgrave Hospital for bronchitis, albuminuria, and right otorrhœa. Two months before this she had had pneumonia, bronchitis, and measles. The attack of bronchitis subsided quickly. Her urine contained much albumin but no casts. A year later she was again admitted for bronchitis and the urine was found to contain a fairly dense cloud of albumin. In November last she was admitted for prolapsus recti. When exhibited she had been an in-patient since Jan. 28th for an attack of bronchitis and anasarca. The face and legs had been moderately swollen for four days. The liver extended 2 in. below the ribs and the spleen was palpable, the abdomen being considerably distended, though there was no dulness in the flanks. The urine contained 0·2 to 0·7 per cent. albumin. A centrifugalised specimen on Feb. 12th showed many white cells, several granular and hyaline and a few epithelial casts. The total daily amount of urine varied greatly—e.g., 12, 22, 30, and 13 oz. on successive days. Von Pirquet's reaction was negative and there was no reason to suspect syphilis. The case was shown with a view of eliciting opinions as to the nature of the albuminuria, the causation of the hepatic enlargement, and the probable prognosis.

Dr. **H. CHARLES CAMERON** read a short paper on Summer Diarrhœa and Summer Heat. Its object was to emphasise the importance of temperature and environment as direct causes of summer diarrhœa, in contradistinction to infection.

SECTION OF ELECTRO-THERAPEUTICS.

The Use of X Rays in the Diagnosis of Pulmonary Tuberculosis.

A MEETING of this section was held on Feb. 21st under the presidency of Dr. **REGINALD MORTON**. The subject for discussion was the Use of X Rays in the Diagnosis of Pulmonary Tuberculosis.

Sir **R. DOUGLAS POWELL** declared that no one appreciated X ray work more than he did, and especially the advances in technique. The use of X rays in connexion with lung disease he understood to be to correct or confirm what was revealed by auscultation and percussion. Dr. Jordan, in a published work on the subject, laid stress on the presence of streaks of shadows in the X ray picture leading from the bronchial glands, and enlargements of those glands, but the speaker did not regard that as necessarily evidence of active tubercle [illegible] found in [illegible] dustbins [illegible] sidered trifles which might gather in the bronchial tubes and get into the lymph streams, and their enlargement need not be held to mean that they were tubercular. Dr. Jordan himself had found tuberculous disease present in 33 per cent. of people who met with an accident when apparently healthy and died. The bronchial glands were also the lethal chambers of tubercle bacilli. Children, and sometimes adults, might have the bronchial glands affected, but rarely primarily. There was some danger of being obsessed by instrument records; hence infinite care was needed in taking and interpreting X ray pictures. How greatly would

---

[1] Brit. Med. Jour., Oct. 5th, 1912.

X rays have helped in early days in deciding whether a case was one of phthisis or one of foreign body. From a simple judgment of shadows a healing fibrosis might be regarded as an extension of disease. To sum up, he considered that X rays were valuable in the case of pulmonary tuberculosis in the sense that percussion and auscultation were valuable; but X ray usefulness did not go beyond that.

Dr. W. J. S. **BYTHELL** (Manchester), in a paper on the Early Diagnosis of Pulmonary Tuberculosis in Young Children by means of the X Rays, gave the results of the X ray examination of nearly 400 children between the ages of 4 and 12, with the object of showing (*a*) the value of the rays in the early diagnosis, and (*b*) the seat of origin of pulmonary tuberculosis in young children. The author laid special stress upon the importance of carefully examining the roots in order to determine the presence or absence of enlarged bronchial glands, and also upon the necessity of distinguishing between active and healed tubercular infections. Attention was drawn to the great frequency of tubercular infection among all classes, and especially among children in the poorer parts of big towns; in most cases the infection was overcome without permanent ill-effects, but probably scars are always left behind, most commonly in the form of calcareous bronchial glands. 150 of the cases were tabulated with the following result:—

Clinical examination.		X ray examination.	
	Positive.	Suspicious.	Negative.
Positive 43	35	5	3
Suspicious ... 67	38	16	13
Negative 40	9	8	23

The author draws the following conclusions: (1) Among poor children in big towns probably the actual majority show signs of tubercular infection of the roots of the lungs; (2) an X ray examination often reveals this fact before there are any physical signs by means of which the clinician is able to make a diagnosis; and (3) the disease appears to commence invariably at the roots of the lungs. In this connexion Jordan's views upon peribronchial tubercular infiltration were discussed with the aid of lantern slides.

Dr. **DAVID B. LEES** said that seven years ago he investigated some cases by auscultation and percussion, and Dr. G. A. Simmons radiographed them, and the conclusion they arrived at was that X rays would not show areas of apical dulness which to his percussion were clearly diseased. But he quite expected that improvement in technique would alter that, and this had proved to be the case. But he thought the value of careful and accurate percussion in incipient pulmonary tuberculosis was much under-estimated; he also thought physicians should cease examining patients while in the erect posture. He did not agree that in the majority of cases, in children at all events, the disease started in the bronchial glands. Post mortem many children were found to have caseous bronchial glands, but with no sign of lung tubercle. The bacilli seemed to pass through the mucous membrane into the glands without leaving any trace of their passage. In a series of cases examined by himself, and independently with X rays by Dr. G. H. Orton, he found the latter accurately confirmed both the presence of the disease and the particular side involved. But he insisted that the radiograph should always be taken by an expert, and great care should be exercised over its interpretation. X rays had also clearly shown a nervous inhibition of the diaphragm in cases of chest disease, so that the patient felt quite unable to take a deep breath when required to.

Dr. A. C. **JORDAN** said that as a result of further observation since publishing his paper he was convinced that hilus or peribronchial tuberculosis occurred even more frequently than he had there stated. In 13 consecutive cases examined at a chest hospital all showed considerable peribronchial mottling, whether the apices were or were not involved. He had never felt impressed by the statement that tuberculosis commenced at the roots of the lungs. The first change was a catarrhal broncho-pneumonia, then followed a leucocyte invasion of the surrounding tissue, and the glands were involved secondarily. In one case he radiographed a patient's lung, and five diseased areas were lettered; shortly afterwards she died from accident, and the post-mortem examination exactly confirmed what he found by X rays.

Dr. W. **PASTEUR** spoke of the new idea that tuberculosis first appeared at the root of the lung and then spread outwards. The new conception should be confirmed by evidence which was irrefutable before the profession was asked to accept it.

Dr **STANLEY MELVILLE** said the attitude of clinicians up to quite recent times might be summed up in a sentence taken from a well-known text-book: "In the early stages of pulmonary tuberculosis the method had been found to be of but little use." Recent work had modified this attitude, and the clinician of the future ought not to rest satisfied until his findings have been fortified or modified by X ray examination. It was impossible to divorce the clinical from the radiographic examination or to regard them as alternative methods. An acknowledgment was made of the debt which was due to early workers on the subject—e.g., Walsham and Orton. What should be taken as the standard of average normal chest? So great a proportion showed opacities at the hilum or linear shadows that they must be regarded as within the limits of health, or the view must be accepted that an overwhelming percentage of the population are, or have been, infected with tubercle. As to the radiographer's type of chest, which is *primâ facie* suggestive of pulmonary tuberculosis, this was considered under the following headings: movement of chest and diaphragm, size of heart (dystrophy), mediastinal contents (glands), significance of linear striation. Dislike was expressed of the term peribronchial phthisis. Why not "central," as in contra-distinction to "apical" or "basal" pulmonary tuberculosis? There was a difficulty in following Dr. Jordan's argument. If definite opaque masses at the hilum + radiating linear opacities were pathognomonic of pulmonary tuberculosis, then they occurred in so vast a percentage of cases as to compel medical practitioners to *notify* about 90 per cent. of the population, and at best the radiographer could only say that they are suggestive of *arrested* tubercle. If his argument is that this condition + definite surrounding mottling suggests activity, then he is stating nothing that radiographers have not appreciated for years—viz, that mottling of lung tissue is the X ray sign of pulmonary tuberculosis, and the activity of the process depends upon (1) the X ray appearance, whether "woolly" or "hard," (2) clinical evidence—e.g., temperature, &c.

The discussion was adjourned until March 19th.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held at the London Hospital on Feb. 26th, Mr. A. H. **TUBBY**, the President, being in the chair.

Dr. P. N. **PANTON** demonstrated cases and blood films illustrating the various types of the Non-granular Leukæmias. Specimens or cases were shown of the following conditions: chloroma, with the blood changes of acute myeloid leukæmia; acute myeloid leukæmia; the myeloblastic stage of chronic myeloid leukæmia; acute lymphoid leukæmia; and three cases of chronic lymphoid leukæmia.

Mr. S. **GILBERT SCOTT** showed some radiograms of Bone Diseases, Innocent and Malignant, also radiograms of Pituitary Tumour, &c.

Dr. **LEWIS A. SMITH** showed a case of Polycythæmia associated with Congenital Morbus Cordis in a boy.

Dr. J. H. **SEQUEIRA** showed a remarkable case of Multiple Lupus.

Mr. **HUGH LETT** showed a case of Cervical Rib. The patient was a woman, aged 27, who had suffered from pain down the inner side of the right arm and forearm for the last two years. The hand got tired more easily than the one on the opposite side, and was very susceptible to cold weather. On examination there was marked wasting of the muscles of the thenar and hypothenar eminences, and also of the interossei. There was some loss of sensation on the inner side of the forearm and hand. The pulse in the right radial artery was smaller than that in the left. No bony tumour could be felt in the neck, but a skiagram showed two bony projections, apparently an inch and a half long extending downwards and outwards from the transverse processes of the seventh cervical vertebra

Dr R HUTCHISON showed 1 A photograph of a girl 3 years of age, who is the subject of Acute Myeloid Leukæmia with infiltration of both parotids and swelling of all the lymphatic glands 2 A case of probable early Acromegaly in a man aged 42 with enlargement of the hands and feet and concentric diminution of the visual fields A radiogram of the base of the skull, however showed nothing abnormal and there was no diminution of sugar tolerance

Mr L J AUSTIN showed 1 A case of Pancreatic Cyst (Mr P Furnivall s case) in a man aged 45 In August 1912 the patient was hit in the lower part of the chest by the pole of a cart and recovered from the accident in a few weeks Some months later a large swelling was region which was tense, globular with respiration The diagnosis pancreatic cyst of traumatic origin 2 A case of Osteitis Deformans (Dr F J Smith s case) The patient aged 50 had noticed changes in his skull for three to four years On examination he presented the following typical signs (1) An irregular bossy head , (2) marked kypho is (3) enlarged and curved tibiæ Most excellent radiograms were exhibited showing the changes in the skull spine and legs 3 A specimen of Chronic Duodenal and Gastric Ulcers (Mr J Sherren s case) The patient aged 61 had had symptoms for about three years and was admitted to the London Hospital with some hæmatemesis and melæna He died before any operation could be performed The specimen showed a chronic gastric ulcer on the lesser curve 4 cm from the pylorus and also a chronic duodenal ulcer on the posterior surface of the duodenum with firm adhesions to the pancreas At the base of this ulcer was seen a ruptured aneurysmal dilatation of the gastro duodenal artery Mr Sherren also provided seven cases of cured duodenal ulcers three of which had perforated at the time of operation Only one had any symptoms of discomfort and in this case perforation had occurred Gastro enterostomy had been performed on all of these and in one case where closure of ulcer only had been performed an enterostomy had to be done subsequently

---

MANCHESTER MEDICAL SOCIETY

Treatment of Syphilis by Neosalvarsan with Wassermann Control —Early Diagnosis of Pulmonary Tuberculosis in Young Children

A MEETING of this society was held on Feb 19th

Mr L SAVATARD dealing with the clinical aspect of the Treatment of Syphilis by Neosalvarsan with Wassermann Control said he was stimulated to a more thorough use of neosalvarsan after hearing McDonagh's paper on a Rational Method of Treating Syphilis in July last Since that time he had treated some 25 cases and given about 100 injections with excellent results In five cases he had administered the drug intramuscularly (according to Wolbarst s method) and though there had been no pain at the time all the patients had suffered afterwards The remainder had all been treated intravenously The greatest care had been taken in the preparation of the patient and of the apparatus McDonagh s syringe was used the neosalvarsan was dissolved in *freshly redistilled* water heated to 100° C and then cooled to 25° C , the dosage varied from 0 6 grm to 0 9 grm All the cases thus treated had apart from their syphilitic affection been otherwise healthy No bad symptoms had resulted and in no instance had there been any rise of temperature The injections had been given in some cases weekly in others fortnightly and in others every three weeks When a *cure* was aimed at, the injection was continued till the Wassermann reaction was negative both before and after the last injection To produce this result in secondary cases at least seven injections had been found necessary Mercury had been administered afterwards The earlier the treatment the sooner was the cure effected Among the secondary cases previously untreated referred to and shown on the screen were macular papular, pustular and frambœsiform syphilides A case of syphilitic leucoderma in a man was also mentioned in which a single injection had effected a symptomatic cure The tertiary cases shown had previously resisted prolonged treatment with mercury and potassium iodide and among these were patients with extensive lesions of the buccal cavity and a malignant syphilide The speaker commended the use of provocative injection in cases of latent syphilis —Dr ARNOLD RENSHAW dealt with the pathological aspect The evolution of the Wassermann reaction was traced from the time when Pfeiffer demonstrated the phenomenon of bacteriolysis Discussing the nature of the antibodies which cause a positive reaction the speaker considered that they could not be true antibodies similar, say, to those present in streptococcal infections since so far as he knew no spirochætæ had been demonstrated as being ingested by leucocytes He maintained that a positive Wassermann reaction is an expression of the amount of liberated endotoxin obtained by the destruction of spirochætæ and its subsequent action upon the cells Whether that reaction was due to the actual disorganisation of the cells brought about in some special chemical manner—possibly a catalytic reaction—by the particular endotoxin set free by the dead spirochætæ had yet to be demonstrated A schematic representation of the life cycle of the organism of syphilis as worked out by McDonagh was next shown and used to explain why in certain stages of the disease a negative reaction was present which would become positive after an intravenous injection of neosalvarsan treatment being continued until the reaction was negative immediately after an injection A comparison between this method and the sterilisation of tetanus spores was made it being suggested that neosalvarsan stimulated the zygotes to develop into a stage in which they might be killed Stomatitis cases usually gave a very strongly positive reaction and where a mouth lesion of any magnitude was present without a slightly positive reaction it should be suspected that the disease had had some other infective process—e g tuberculosis—superadded, or that the condition had progressed to the stage of carcinoma

Dr C P LAPAGE read a paper on the Early Diagnosis of Pulmonary Tuberculosis in Young Children with Special Reference to the Value of X Rays as an Auxiliary to Clinical Examination He drew attention to the frequency of pulmonary tuberculosis in children and to the evidence which showed that the disease was so often at the roots of the lungs He described the conditions which gave most difficulty in diagnosis (1) Active open disease at the roots , (2) active disease limited to the bronchial glands , and (3) healed disease in the lungs with some superadded condition giving general symptoms resembling those of tuberculosis Having noted the fact that with ordinary clinical methods it was often impossible to make a definite diagnosis owing to the absence of physical signs he demonstrated the value of the X rays in clinching a diagnosis based on suspicious symptoms only The results of the examination of 150 cases, most of them chosen because of their suspicious condition clinically was given in tabular form The table showed the relation between the clinical and the X ray examination as made independently by clinician and radiographer Dr Lapage upheld the great value of the X rays in these cases as a supplement to the clinical examination, and pointed out the importance of establishing the normal screen picture of the thorax —Dr W J S BYTHELL first dealt with the nature of the evidence afforded by an X ray examination directing attention specially to the importance of thoroughly examining the appearance of the roots of the lungs In his opinion the normal streaky markings visible in all lungs might be increased by bronchitis, and he regarded shadows due to enlargement of the bronchial glands or to pulmonary consolidation as the only reliable signs of tuberculous infection As the result of 300 or 400 examinations he had made he concluded that the majority of children living in our large towns present evidence of the tuberculous infection after the age of 6 to 8 years In most cases the glands were able to overcome the bacilli but should they caseate and break down the infection extended directly to the adjacent lung tissue and led to a tuberculous broncho pneumonia originating at the hilus of the lung In any case he was strongly of opinion that pulmonary tuberculosis in children commenced in the vast majority of cases, if not invariably at the root of the lung In the earliest stages of this root disease definite indication of the lesion might often be discovered by means of the rays when no physical signs were to be detected

LIVERPOOL MEDICAL INSTITUTION.

Recurring Dislocation of the Shoulder.—X Ray Examination of the Stomach.—Some Points in Modern Eye Practice.

A MEETING of this society was held on Feb. 20th, Mr. ROBERT JONES, the President, being in the chair.

Mr. T. R. W. ARMOUR read a note on two cases of Recurring Dislocation of the Shoulder in which "Clermont's" operation had been performed by Mr. Robert Jones. The first patient had had his right shoulder dislocated 76 times and his left 26 times. He had had capsulorrhaphy performed on both joints without success. The operation consisted in bringing a long flap of the posterior margin of the deltoid through the quadrilateral space in front of the capsule of the joint and stretching its end in front under the coracoid process. This deepened the socket and tightened the capsule. Care was needed to avoid injury to the nerve and arterial supply of the muscle. In the first case the operation performed in June last year had not been a success. The second case was done last November, and so far had been quite satisfactory. Mr. Robert Jones said that the first case had failed from faulty technique; the deltoid flap had not been long enough and the tunnel not wide enough to allow easy manipulation; also the fixation of the flap had not been sufficient to prevent the flap of muscle returning to its original place. In the second case care had been taken in these points, and so far with good result. The operation was only on its trial.

Mr. C. THURSTAN HOLLAND read a short paper on X Ray Examination of the Stomach. From one-half to three-quarters of a pint of bread and milk, of the consistence of bread-sauce, mixed with three or more ounces of carbonate of bismuth, or barium sulphate, which was much less expensive, was given to a fasting patient. The stomach was then seen to be much longer and narrower than was depicted in anatomical works even of recent date. The lower end came to the level of the iliac crest, and the whole organ was to the left of the middle line. The movements were rhythmical, at the rate of 1 in 20 seconds, and did not go through into the duodenum. The food did not lie at the lowest part of the stomach, but was distributed through the length when full. The normal stomach emptied in about 3½ hours after this test meal. Mr. Holland showed photographs on the lantern screen of the normal stomach and its variations and contractions: three cases of transposed viscera; cases where gastric enterostomy had been done; cases of gastroptosis; of dilated stomach, in which he showed the lower end of the stomach was quite in the pelvis; also cases of malignant disease and of hour-glass contractions of the organ.—Dr. T. R. BRADSHAW said that physicians recognised Mr. Holland as an expert authority and welcomed the immense aid that the X ray method gave in diagnosis in very many cases.—Dr. J. HILL ABRAM said that the physician would still be obliged, especially in places remote from elaborate equipment, to rely on the older methods of diagnosis, while they, of course, welcomed the confirmation and help that radiographic methods afforded.—Mr. J. BRADLEY HUGHES and Dr. R. J. M. BUCHANAN also spoke, and Mr. THURSTAN HOLLAND replied.

Dr. EDGAR STEVENSON read a paper on Some Points in Modern Eye Practice. In speaking of therapeutic agents, he said that he had found cocaine hydrochlorate the most useful of the group of local anæsthetics. He thought that a weak mydriatic, such as homatropine, was safer than the stronger preparations. Among silver preparations the nitrate was the most useful. Subconjunctival injections of oxychloride of mercury had been found useful in septic cases. Of internal remedies, aspirin in trauma and in iritis cases, and sodium salicylate in large doses in sympathetic ophthalmia had been of service. Dr. Stevenson's experience of salvarsan, of vaccines, and sera had not been very favourable. Of physical remedies, he condemned cold applications as dangerous, and found heat more useful. He still found depletion by leeches of great benefit. Time did not permit the whole paper to be read, but Dr. Stevenson showed two preparations illustrating Tote's operation for dacrocystitis.—Mr. T. H. BICKERTON disagreed with the use of nitrate of silver in gonorrhœal ophthalmia; he had used none for 16 years. He used iced compresses, and had never lost an eye.—Mr. W. T. CLEGG called attention to the omission of urotropine, which he had found useful in wounds of the eye. He did not think subconjunctival injections were better than ordinary subcutaneous injections. In the treatment of dacrocystitis he was satisfied with the older methods of treatment, and thought that excision of the sac should be of very limited application.—Dr. A. NIMMO WALKER agreed with Dr. Stevenson in his condemnation of the use of ice pads in gonorrhœal ophthalmia, and was convinced that warm moist applications were the best in the acute stage. He had not tried bloodletting in glaucoma. In a routine examination of the blood pressure in cases of chronic glaucoma he had failed to find any definite relationship between changes in circulatory and ocular tensions. In dacrocystitis slitting the canaliculi and probing were worse than useless. The new operation described by Dr. Stevenson was well worth trying.—Mr. E. MALCOLM STOCKDALE agreed that the old-established drugs, such as cocaine, atropine, and boric acid, still retained their place in eye work. The use of silver nitrate solutions, he thought, should always be very limited and applied with the greatest care. In gonorrhœal ophthalmia the infection, being at first on the surface, could be washed away by a mild lotion, such as boric acid. In advanced lacrymal disease he had found excision of the sac to yield satisfactory results.—Mr. R. E. HARCOURT and Dr. J. R. LOGAN also spoke, and Dr. STEVENSON replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

The Adequate Stimuli of the Respiratory Centre.

A MEETING of this section was held on Jan. 24th, Dr. B. J. COLLINGWOOD, the President, being in the chair.

Professor T. H. MILROY read a paper on the Adequate Stimuli of the Respiratory Centre. He described the methods of studying the influence of nervous factors in the production of apnœa, and also the effects of various gas mixtures on the quiescent centre. The following conclusions were tabulated: 1. Alterations in the rate or degree of distension of the pulmonary alveoli when the amount of ventilation is constant do not affect the duration of the apnœic pause in any constant direction, but a repetition of ventilation periods tends to prolong the pause. 2. Removal of the vagal control does not interfere with the production of the apnœic pause. 3. Any rise in the CO_2 content of the air used for ventilation shortens the apnœic pause, and any increase in the carbonic acid content of the gas mixture used to distend the lung after pulmonary ventilation with air shortens the period. With increased CO_2 content of these gas mixtures irrespective of the amount of oxygen, the apnœic pause proportionately decreases. 4. Injection of small quantities of acid solutions directly into the carotid during the pause leads to respiratory movements of an exaggerated type, as does also injection into the central end of the carotid and into the external jugular vein to a lesser degree. 5. With the excitation of such respirations during the pause there is associated an increased passage of carbonic acid from pulmonary blood to air. 6. These effects are produced after removal of the vagal control, but the excitability of the centre under such conditions seems to be diminished. 7. The passage of CO_2 from alveolar gas mixtures to blood, or from blood to alveoli, seems to depend entirely upon the difference of the pressure of that gas in the blood and air in the alveoli. 8. It seems most probable that the effective stimulus of the respiratory centre rendered quiescent by over-ventilation is a rise in the carbonic acid concentration in that centre, whether brought about by the normal rise in carbonic acid formation during the pause, with its associated rise in the CH_1, or primarily to a rise in the CH_1 from the formation of acid products of incomplete oxidation giving rise secondarily to an increase of the free CO_2 tension.—Professor W. H. THOMPSON, Dr. O'CONNOR, and the PRESIDENT spoke, and Professor MILROY replied.

Mr. J. M. M'MAHON gave a demonstration of the action of Thrombin and Antithrombin.—The PRESIDENT pointed out that this preparation of thrombin acted equally well in purpura hæmorrhagica and in hæmophilia.—Mr. E. L. SHERIDAN said that he had used this preparation with success for persistent bleeding after extraction of teeth.

Professor THOMPSON described some New Standard Solutions for the Estimation of Creatinin by Folin's Method, and also described a Modification of Benedict's Method for Estimating Urea —The PRESIDENT and Professor MILROY spoke, and Professor THOMPSON replied

SECTION OF OBSTETRICS

Rupture of the Uterus —Wertheim s Hysterectomy —Surgical Treatment of Pelvic Thrombosis of Septic Origin

A MEETING of this section was held on Feb 7th, Dr A J HORNE the President being in the chair

Dr D G MADILL showed two cases of Rupture of the Uterus Case 1 was a multipara aged 34 who was sent into hospital in a collapsed state with a history of having been in labour nine hours Her pains increased in strength for about seven hours, when she got a very severe pain, after which all pains ceased The fœtus could be easily palpated in the abdominal cavity On opening the abdomen the fœtus was found to have left the uterus—all except the head —through a large rent extending from a third way up the uterus on the left downwards and outwards along the base of the left broad ligament The placenta was loose in the uterus, and there was a good deal of intraperitoneal hæmorrhage Supravaginal hysterectomy was done and the patient recovered The second case was a multipara aged 32 Previous labours normal After she had had pains off and on for a fortnight the doctor tried to apply forceps three times, but failed She was then sent into hospital in a moribund state Palpation disclosed the fœtus free in the peritoneal cavity The extremely collapsed condition of the patient prevented immediate operation When the abdomen was opened both fœtus and placenta were found to have left the uterus and an enormous rent was discovered on the right side of the uterus extending down and half way across the cervix in front and behind There was a great deal of intra- and subperitoneal hæmorrhage The bladder was badly torn Hysterectomy was done as rapidly as possible, but the patient succumbed just as the operation was concluded In Case 2 the cause of obstruction was hydrocephalus the baby in addition weighing 9¼ lb In Case 1 the patient had a very pendulous abdomen, and obstruction was probably due to the misdirection of the uterine contractions against the promontory instead of through the brim —Dr H JELLETT pointed out that in the first case Dr Madill had successfully operated on a patient although the child had passed from the uterus into the peritoneal cavity A well known obstetrician had stated that he had never seen a case of uterine rupture such as this where the patient was saved He (Dr Jellett) had reported a similar case to this section during the last session In that case the same treatment was adopted as Dr Madill had adopted, and the patient got perfectly well —Dr B A H SOLOMONS recalled a case in which rupture of the uterus had resulted from a neglected brow presentation, and the body of the child was in the abdominal cavity The child was delivered by forceps, the placenta manually removed and the rent in the uterus plugged with iodoform gauze The patient got quite well Various modes of treatment had from time to time been reported as successful, but it seemed nearly impossible to lay down a definite treatment without seeing the individual case —Dr R D PUREFOY said he had seen and assisted with the two patients He considered it proper that all these cases should be brought forward as most handbooks were calculated to lead younger members of the profession to believe that warning symptoms always preceded the catastrophe

Dr E H TWEEDY exhibited a specimen of Cancer of the Uterus in a patient aged 38 When she first consulted him she stated that she fainted [illegible] The vagina was plugged a [illegible] hospital, but she continued [illegible] he found the entire lip of the cervix malignant She was curetted, but very little came away There was no pain nor history of discharge The uterus was mobile, and ulceration had not taken place There was no cachexia Wertheim's hysterectomy was performed and on opening the uterus a small myoma was found with a blood clot round it which was the cause of the bleeding But for this myoma the patient would not have come up with the cancer Just before closing the abdomen a mass of very adherent glands was found far away from the original growth —Dr PUREFOY said it had long been believed that malignant disease of the cervix became a danger to life early in the progress of the case, and the implication of distant glands in this patient confirmed that view

Dr JELLETT read a paper on the Surgical Treatment of Pelvic Thrombosis of Septic Origin, dealing first with the essential differences between acute and chronic pyæmia He referred to a patient who had died last year in the Rotunda Hospital from pyæmia with thrombosis of the ovarian vein as shown at the post mortem examination He consequently decided to operate on future cases of a similar kind He then recorded three such cases in all of which the initial history was characterised by recurrent rigors, high temperature, and rapid pulse In conclusion, he referred to the interesting fact that in all his cases the thrombosis was on the right side and primarily in the ovarian vein alone Consequently, they were favourable cases for operation He considered that such cases called for operation always and that it should be as early as possible The diagnosis he said was the important point, and that, as a rule this could be made from the symptoms, taken in connexion with thickening or swelling in the broad ligaments, and associated with the comparatively little pain or tenderness —Professor A J SMITH said that anything which went to advance knowledge of the operative treatment for thrombosis of the pelvic veins represented a distinct step The opinion amongst those who had operated seemed to depend more on the conditions found bimanually than on the rise of temperature and comparatively slow pulse —Dr J S SHEILL suggested that the fact of infection taking place more frequently on the right side than on the left was attributable to the fact that most examiners were right handed, and the tendency was for the examining finger to be brought to the right side of the patient and that possibly ulceration of the cervix might have taken up the infection thus —Mr C Y PEARSON considered that the operation was justified whether there was thrombosis present or not On anatomical grounds it was to be expected that the uterine vessels would be open to infection more than the ovarian veins With regard to the technique, before proceeding to follow up the veins the first step should be to expose the ovarian vein where it entered the vena cava or left renal vein and divide it It was, he thought, important to start as far away as possible from the focus of infection There was a great danger of embolism if the general circulation was not shut off before attacking the septic parts He had found vaccines of little use in cases of acute infection, but he had seen serum do good —Dr R J ROWLETTE spoke of the generally unsatisfactory results of vaccines in thrombosis He thought that the reason was that in nearly every case of thrombosis there was a mixed infection He had recently, however, had two cases where vaccine was the only treatment adopted and was successful One was a case of acute puerperal melancholia and pyæmia, and an autogenous staphylococcus aureus vaccine was given with quite satisfactory results The second case was much more serious, and one in which he thought at first that any treatment would be hopeless There was thrombosis, and there were infarcts in the lungs, and in the opinion of those in charge of the case the patient was hopelessly ill when the treatment was started A growth of streptococci was obtained from the venous blood and a vaccine prepared. The temperature and pulse came down step by step and the general condition improved In a week the patient was convalescent, and though an attack of pleurisy supervened she recovered completely It was one of the worst cases of puerperal sepsis he had ever seen —Dr PUREFOY considered that Dr Jellett was correct in stating that 60 or 70 per cent did not recover The most interesting case was that in which the ovarian artery showed marked degenerative changes This had not been previously recorded Two recent writers mentioned three cases of the kind in which operation was carried out without success and they laid down the principle that where organisms were found only during rigor, operation was indicated and would probably be successful, but where the organisms were found at any other time operation was not indicated —Dr JELLETT in reply, recognised that the question of operation in these cases was still one for very grave discussion but that in cases such as those he brought forward it was positively indicated

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 18th, Dr. Morgan Dockrell presiding.—Dr. J. L. Bunch showed a case of a man, aged 50, with a Marked Symmetrical Dupuytren's Contraction of the Fingers which was remarkably hereditary, as the same condition had existed in his family for the past 300 years. It commenced about the age of 25 and reached the maximum at about 40. His father, grandfather, and so on, had had exactly the same lesions, and his two sons both had it—one aged 26 was just starting.—Dr. Bunch also showed the case of an old woman with some Scarring on the Nose and a small Tumour on the Back of the Neck—the former either tubercular or syphilitic and the latter a cyst.—The President, Mr. D. Vinrace, Dr. R. Prosser White, Dr. W. Griffith, Dr. W. Knowsley Sibley, Dr. W. W. Wells, and Dr. J. L. Phibbs discussed the cases.—The President showed a case of a man with some Old-standing Specific Scars and Depressions on the Scalp, the severity of which he considered was associated with a tubercular soil.—Dr. Griffith showed a man who presented a Diffuse Area of Livid Red Skin, involving the whole of the bathing-drawers area. The Wassermann reaction was negative, and histologically it presented the condition of parakeratosis, and he considered it one of the erythrodermias.—Dr. Sibley showed a case of advanced Leucoderma in a girl 18 years of age. The treatment consisted in increasing the pigment in the pale areas by local hyperæmia and removing it from the pigmented ones by lotions of perchloride of mercury applied by ionisation.—Dr. Sibley also showed a case of extensive Scrofuloderma in a girl aged 9; some of the lupus lesions he was treating with ether carbon dioxide, and others with ionisation of sulphate of zinc solution.—Dr. Prosser White read a paper on the Sociological Aspects of Syphilis, in which the point was emphasised that the first thing to enable a disease to be controlled was to know its extent. In Scandinavian countries compulsory notification of syphilis was enforced, its seriousness only too well recognised, and rational attempts were made to check it. It was the opinion of many that venereal disease was more disastrous to the health of a country than either tubercle or alcohol, and he compared the apathy towards the former with the public and private interest in the two latter questions. Again, syphilis was much more easily controlled by treatment than either of these. Modern intensive treatment by healing up the early and secondary lesions of syphilis make this treatment a valuable and prophylactic measure. The continent, America, and our colonies were demanding free treatment by experts. How long must we delay?—The President, Dr. Sibley, Mr. Vinrace, Dr. Griffith, and Dr. E. G. Reeve joined in the discussion.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Liverpool on Feb. 21st, Dr. W. E. Fothergill (Manchester), the President, being in the chair.—Dr. J. E. Gemmell (Liverpool) showed a specimen in which the vermiform appendix was adherent to the right Fallopian tube. The left appendage had formed a tubo-ovarian abscess. The right tube and appendix were so intimately connected, and the history of two abortive attacks of appendicitis so definite, that the primary mischief was probably appendicular.—Dr. T. B. Grimsdale (Liverpool) showed a specimen of Carcinoma of the Body of the Uterus from a patient whose ovaries were removed three years previously and which were reported upon at the time as being suspicious of malignancy, though not definite.—Dr. Gemmell showed two cases of Ectopic Gestation. 1. A secondary abdominal pregnancy with a seven months' fœtus and with a very clearly defined history. 2. An isthmal pregnancy in the left tube of six weeks' duration, which
and ed very severe intraperitoneal hæmorrhage. The abdo-
opht l ostium was free from blood clot or appearance of drip,
rienc o rupture could be found on the tube.—Dr. W. Fletcher
very w (Manchester) showed a Fibromyoma of the Uterus
colc plicated by an abscess in the right broad ligament
usef- which a pure culture of streptococci was obtained.
Time years previously the patient had a septic mis-
Dr. S re, but had had good health from that time until
operat dden onset of th [illegible] ammation.—Dr. W. Blair
with the erpool) crate of silver in of Superinvolution of
he had used none for 16 years. He re. The patient was
and had never lost an eye.—Mr. W. The birth of her first
tion to the omission of urotropine, wn a few weeks and the thyroid enlarged, all the symptoms of exophthalmic goitre developing in a short time. The uterus was very small, the cavity being only 2 inches in length. The case was of great interest owing to the fact that superinvolution appeared more likely to follow deficient thyroid secretion than the reverse.—Dr. Catherine Chisholm (Manchester) read a paper on the Nature and Extent of Menstrual Molimina during Adolescence, based upon the menstrual history of 500 girls attending school between the ages of 10 and 20. The majority, 58·6 per cent., experienced no discomfort. In 33·6 per cent. the pain was slight and often only occasional: those suffering discomfort experienced rather local symptoms than general disturbance, such as headache or general lassitude. The tendency to disturbance did not appear affected by the age of onset. Severe cases of pain, so far as there was opportunity for examination, were associated with local abnormalities. The largest number of cases with discomfort and pain occurred among anæmic girls with profuse loss. The best physically developed girls showed over 70 per cent. without any disturbance and with no cases of pain which incapacitated them from work. Hard mental and physical work under healthy conditions did not appear to affect the freedom from menstrual disturbance.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 12th, Dr. Walter C. Swayne, the President, being in the chair.—Dr. F. H. Edgeworth, in opening a discussion on the Treatment of Chronic Constipation, said that constipation might exist with a daily opening of the bowels. Delay in passage of the intestinal contents over the normal 40 hours could be easily shown by the administration of charcoal biscuits to colour the fæces. He had found that salines were particularly efficient in patients with high blood pressure and that while cascara to retain its effects must be given in increasing doses, aloes need not. In cases combined with neurosis he had found bromides efficient, and in cases in which the chief difficulty was emptying the lower bowel enemata had to be used, glycerine being unsuitable for constant use owing to its injurious action on the mucous membrane.—Mr. T. Carwardine said that he had been able to cure several cases by the division of adhesions in the ileo-cæcal region, but he was doubtful as to the advisability of performing such extensive operations as removal of the colon.—Mr. F. G. Bergin pointed out that by locating the situation in which delay occurred a bismuth X ray examination was of great help towards correct treatment.—Dr. Bertram M. H. Rogers regarded constipation in children and infants as the result of bad habits, combined with a deficiency of fats in the food, and particularly of water.—Dr. J. Michell Clarke regarded neglect in childhood as the most frequent cause, and insisted on a routine rectal examination in cases of constipation.—Mr. Lansdown had once been asked to remove the colon to cure a case of constipation, but had given relief by removal of enlarged ovaries impacted in the pelvis.—Mr. J. L. Firth had treated a chronic case by appendicostomy and lavage, but had been compelled later to remove the colon.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held in the Radcliffe Infirmary on Feb. 14th, Dr. W. Duigan, the President, being in the chair.—Mr. A. P. Dodds-Parker showed the following series of cases of Fracture treated by modern methods: 1. Fracture of upper end of humerus in a young man, treated by a Lane plate; perfect result. 2. Fracture of olecranon in a woman, treated by wiring; very good result. 3. Fracture of olecranon in a man, treated by wiring; very good result. 4. Fractured femur in a boy, treated by a Hodgen's splint; perfect result, no shortening. 5. Fractured tibia in a man, treated by a Lane plate; there was delayed union and much callus, but a good result. 6. Fractured humerus of the middle third in a man, treated by a Lane plate; good result. 7. Fractured tibia and fibula in a man, treated by a Lane plate for non-union; good result. 8. Fractured patella in a man, treated by a wire and a Lane plate; good position of the patella, and walks well. 9. Fractured ulna and radius in a man, treated by a Lane plate; good result. All the cases were illustrated by X ray photographs before and after, taken and demonstrated by Mr. R. H. H. Sankey.—Dr. W. J. Turrell then showed a case of Lupus of the Cheek in a woman who had had no treatment for 12 years, whom he was in process of treating by diathermy. Five applications had been given and the effects of various intensities of the treatment were demonstrated in a piece of fresh liver tissue.—Dr. W. Collier related the histories of two unusual cases of Diphtheria: the first in a woman, aged 28, who entered the Radcliffe Infirmary for chorea of pregnancy. The patient became maniacal, and as the child was viable labour was induced. The patient recovered from this, but had a parotid abscess in which staphylococci were formed. Later, six weeks after her entry into hospital, her voice became husky, there was respiratory stridor, and she died. At the post-mortem examination a diphtheritic membrane in which B. diphtheriæ was found extended from the vocal cords to below the bifurcation of the trachea. The second case was a nurse who had been in attendance on a very bad case of septicæmia, the nature of which had not been exactly determined. The patient subsequent to leaving the case developed a high temperature, great cyanosis, and rapid failure of strength. There were a few râles in the chest and some sputum in which B. diphtheriæ and numerous cocci were found but none of the ordinary clinical signs of diphtheria. Antidiphtheritic serum was without effect. At the post-mortem examination diphtheria bacilli were found in the mucus of the trachea and smaller bronchioles. The lungs were œdematous and partly solid, but did not sink in water; no other lesions were found.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 28th, Dr. J. F. Dobson, the President, being in the chair.—Dr. W. Cuthbert Morton read a paper on the Present Crisis in Anatomical Nomenclature. The Basel nomenclature, which was promulgated by the German-speaking anatomists in 1895, had made such progress in America and the Colonies, and even in Britain, that the Anatomical Society had been forced to discuss its adoption, not merely as an international code, but for ordinary use. There were grave objections to the Basel nomenclature. It did not claim to be more than a list of names acceptable to German-speaking anatomists, and requiring to be submitted to anatomists speaking other languages. In spite of much that was excellent, the principles on which it was based were not scientific, and it did not sufficiently regard the needs of medicine and surgery. Moreover, in some respects it was not up to date. Dr. Morton, therefore, pleaded for a commission of British anatomists and teachers of final subjects to prepare a complete British nomenclature as far as possible in harmony with the Basel nomenclature. An international conference might then be called to evolve a truly international nomenclature. He rapidly reviewed the principles upon which such a nomenclature should be based, and sketched out the manner in which these principles might be applied to the abdominal cavity and its contents.—Mr. J. Stewart showed specimens from six recent abdominal operations illustrating the difficulties of diagnosis.—Mr. Alexander Sharp showed a specimen of Squamous-celled Carcinoma of the Larynx.—Mr. G. Constable Hayes showed a specimen (with photograph) of a large Osteoma which caused secondary mastoid disease in a case of suppurative otitis media.—Mr. Walter Thompson exhibited a large Malignant Tumour of the Bladder which had been successfully removed by a wide operation. Recurrence of the growth had, however, taken place after an interval.—Dr. C. W. Vining showed a case of Hysterical Stupor which was improving under treatment.—Mr. H. Littlewood showed a specimen of Tuberculous Mesenteric Glands which he had removed by operation. There had been a sinus communicating with the surface, and he had removed the sinus, glands, mesentery, and associated loop of bowel, performing an end to end anastomosis. The patient had made a good recovery.—Cases and specimens were also shown by Dr. J. B. Hellier, Mr. L. A. Rowden, Mr. E. W. Bain, and Dr. M. J. Stewart.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of the society was held on Feb. 18th.—A discussion on Puerperal Eclampsia was introduced by Dr. E. W. Sharp. He defined the term, insisting that the "fit" was a common symptom, and not the whole disease. This was a toxæmia in which certain well-marked pre-eclamptic manifestations, notably headache, disturbance of vision, swelling of face and of extremities, and diminution in amount of urine, were commonly observed. The condition was quite distinct from uræmia and albuminuria, and the toxin was not microbic. It had been shown to be akin to certain venoms in that it contained the same five elements, thrombotic, hæmolytic, hæmagglutinative, endotheliolytic, and neurotoxic. Although eclampsia was apt to recur in subsequent pregnancies it did not result in permanent nephritis. It occurred in sterile molar pregnancies as well as in normal ones. It was believed by some to be due to imperfect balance of the internal secretions, those of the suprarenal and pituitary being increased, as evidenced by high blood pressure, a prominent feature of the disease, and that of the thyroid diminished. The retention of the poisonous products was, according to authorities, favoured by nitrogenous food, bile, intestinal putrefaction, and toxins were due to metabolism of maternal and fœtal cells. Prophylaxis was of the greatest importance in preventing the eclamptic attacks; when premonitory symptoms occurred rest, a strict milk and vegetarian diet, and a daily action of the bowels were essential. When the attacks occurred Tweedy's methods were to be followed. The avoidance of external stimuli, the use of morphia, elimination of toxins by lavage of stomach and colon were important measures. A concentrated solution of magnesium sulphate should be left in the stomach and a pint of bicarbonate solution in the rectum. Attempts should be made to lower the blood pressure; in many cases venesection was valuable, as was veratrum viride or nitro-glycerine. Where intravenous infusion became necessary bicarbonate solution was better than normal saline. If swallowing were possible frequent draughts of water should be given, but no food. Diaphoresis was not recommended, and lumbar puncture was useless. Dr. Sharp was not in favour of inducing labour. When it occurred it should be assisted, but not forced, natural delivery being preferable to artificial methods. Accouchement forcé was not good practice. When the os would not dilate and pains were strong Cæsarean section was greatly to be preferred.

Reviews and Notices of Books.

Manual of Human Embryology. Edited by FRANZ KEIBEL, Professor in the University of Freiburg i. Br.; and FRANKLIN P. MALL, Professor of Anatomy in the Johns Hopkins University, Baltimore, U.S.A. Vol. II. With 658 illustrations. London and Philadelphia: J. B. Lippincott Company. 1912. Pp. 1032. Price 30*s.* net.

EVERYONE who has to study embryology from whatever aspect—and there are many—can but be deeply grateful to those writers who have contributed to make this work so great a success. It is a compendium of practically all that is known regarding the development of the various organs of the human body. Moreover, the literature is given so copiously that whatever is not fully set forth in the text can easily be traced in the original papers. The illustrations are a most commendable feature of an undertaking of very great scope. The following are the subjects the development of which is dealt with in succession:—The Nervous System, by G. L. Streeter; Chromaffin Organs and Suprarenal Capsules, by E. Zuckerkandl; Sense Organs, by F. Keibel; Digestive Tract and Respiratory Organs, by O. Grosser, F. T. Lewis, and J. P. McMurrich. It should be noted that to Professor McMurrich is due the excellent translation of the chapters by Keibel, Felix, Tandler, and Zuckerkandl. C. S. Minot, H. M. Evans, J. Tandler, and F. R. Sabin are responsible for the chapter on the Blood, the Vascular System, and the Spleen, while W. Felix deals with the Urogenital Organs. Professor Keibel, at the conclusion of the volume, devotes a short chapter to the Inter-relation of the Various Developmental Processes. The subject index is particularly full. There is also an index of authors.

The story of the development of the nervous system is a masterly section and might well be reprinted as a separate monograph for those who are specially interested in this subject. It has also a particular interest for physiologists, apart altogether from the morphological side which is dealt with in a text-book on embryology. The experiments of Harrison carried out on amphibian larvæ are of the utmost importance in regard to the development, and therefore to the regeneration, of nerve fibres, for he showed that no peripheral nerves would develop in an embryo in which the nerve centres had been destroyed. Moreover, axis-cylinders will develop and extend out in the surrounding tissues in the normal way, and will reach their normal length where the sheath cells of Schwann have been eliminated. Nerve fibres also, when the environment is modified, may under certain conditions establish completely foreign connexions. The vast importance of what Ranvier pointed out as the method of "pushing"—i e., as regards growth—is well illustrated both in the text and by the reproduction of some of Harrison's figures. It is an immense stride to be able to grow ganglion cells outside the body in such an organic medium as clotted lymph, where all contributions on the part of other living tissues are eliminated. Indeed, by direct inspection, the growth of a nerve fibre from a ganglion cell as it develops hour by hour is an objective reality. As to the "myelinisation" of nerve fibres, at least where human material is concerned, there is no adequate description yet available. The pig and sheep so far have formed the basis of our knowledge on this subject. We commend to the consideration of neurologists and embryologists the diagrams showing the reconstructions of parts of the nervous system obtained by a careful study of sections of embryos at different ages.

As to those small but wonderfully potent organs grouped under the rather obscure title "chromaffin organs," no better choice could have been made to explain their development from their original "anlagen" than Professor Zuckerkandl, of Vienna. Professor Keibel's account of the sense organs is particularly painstaking and full of detail, as is to be expected from one who himself has contributed so largely to this subject. The illustrations are particularly well reproduced. Especially interesting is the account of the progression and retrogression of certain vessels in connexion with the formation of the eye. Apart altogether from the morphology of the digestive system, the histologist will find much to interest him in the chapter on the development of the digestive tract, more especially as regards ciliated epithelium. Every teacher who has to set forth to his students the development of the intestinal canal should take cognisance of the models referred to in the Harvard collection, illustrations of some of which are given by F. T. Lewis. When we turn to the chapter on the blood we are told by Professor Minot that the scientific interpretation of the theme, as viewed from the clinical standpoint, leaves much to be wished. According to Professor Minot, to clinical writings we owe a confusing nomenclature of the blood corpuscles which sins against every morphological principle. We are glad to read such a comprehensive account of the all-too-much-neglected lymphatic system—a system so easily demonstrated to the student, at least as regards its main tracks. We particularly commend Miss Sabin's contribution on this subject to surgeons and physicians.

We have said enough to show how interesting and directly practical is this comprehensive and up-to-date contribution to the ever-advancing subject of embryology, and in saying so we wish to thank the authors as well as the publishers for the successful issue of their joint enterprise.

Patologia e Terapia Chirurgica dei Calcoli della Vescica Urinaria. By Dott. Mario Schiavoni, Professor of Surgical Pathology in the University of Padua. With a Preface by Professor D. B. Roncali. With 134 illustrations. Turin: Unione Tipografico-Editrice. 1912. Pp. 592. Price 15 lire.

Professor Schiavoni has limited the scope of his extensive treatise to calculus of the bladder, and the work, if only owing to its size, will at once occupy a prominent place in modern literature on this subject. The physical characteristics of calculi are first dealt with, and examples and woodcuts are given of unusual forms. Spontaneous fragmentation is described at length. Various theories of its causation are discussed by the author, who is of opinion that the explanation is to be found in segmentation of the calculus, that all the theories afford a true solution in some circumstances but not in others, and that further actual experiments on fresh, recently extracted calculi are necessary.

Chapters are devoted to the structure of calculi and the various foreign bodies which may cause their formation. Urinary sediments and the chemical constituents of calculi are investigated, the researches of Golding-Bird, Marcet, Henry and B. Smith being largely quoted. The chemistry of these constituents is fully dealt with, as is also the technique for investigating them. The etiology of cystolithiasis is the subject of two chapters, and the part played by heredity, age, sex, occupation, climate, and food, also its relation to other conditions such as bilharzia, echinococcus, actinomycosis, gout, renal infarcts, osteomalacia, and phosphaturia. Stress is laid on the greater frequency of oxalate of lime calculi in children; the influence of poverty and squalor which compel a diet largely vegetable is alluded to as well as the use of acid and fermented beverages containing a considerable proportion of oxalic acid. Attention is also drawn to Ebstein's theory of the frequency and importance of renal infarcts in children. The part played by diathesis is not so much a predisposition to the formation of calculi as a contributory to their chemical constituents. An analysis is given of all the theories of calculus formation, from that of Mariano Santo in the fifteenth century to the present day, including those of Heller, Ultzmann, Meckel, and Ebstein. The author's own opinion is that the origin both of primary acid and alkaline lithiasis may be either renal or vesical, the former being more usual; secondary lithiasis, however, has more frequently its origin in the bladder.

A very interesting group of subjects is well treated in Chapter IX., dealing with the pathological anatomy of cystolithiasis, in which are minutely described the anatomical changes in the urinary bladder when affected by stone. It includes bacteriuria, acute and chronic cystitis, pericystitis and leucoplasia, which are treated at much greater length than in most works on diseases of the bladder, vesical ulceration and fistula, tuberculous and bilharzic cystitis, diverticula and hernia; the relation of neoplasms to calculi is also adequately discussed. In the part dealing with the symptoms and diagnosis of calculus, Guyon's sound is recommended for exploration. Radiography is advocated only for children and as a supplementary method, since absence of any shadow excludes the presence of only oxalic and phosphatic calculi. As regards prognosis, the author draws attention to the gravity of stone as a complication of pregnancy, for it possibly induces rupture of the uterus; he does not, however, give any statistics or cases in support of this view.

An interesting chapter is that on the history of the methods of cutting for stone from the remote times of surgery to the present day, methods known to the Indians, as shown by the *Ayur-Veda,* but probably unknown to Egyptian and Jewish surgery. After an introductory chapter on the anatomy of the perineum, amply illustrated by woodcuts after Testut, perineal cystotomy is described, as well as the operations of median and lateral lithotomy as performed by Civiale, Dupuytren, Nélaton, Albarran, Montenovesi, Sanson, and others. A critical comparison, written with excellent judgment and impartiality, sums up in favour of Montenovesi's technique. There is a clear and concise description of perineal cystotomy, profusely illustrated, and a chapter on after-treatment and complications such as incontinence of urine and complete sterility. In two chapters are described the suprapubic operation, both by longitudinal and the transverse incision of Ledran, and the modifications introduced by Legueu, Vidal de Cassis, and Langenbuch; of these the author considers the last two incontestably the best. Drawing a comparison between the suprapubic and perineal operations, he gives the preference to the former as offering the greater advantages in dealing with large stones. Lithotripsy and litholapaxy are described, a number of lithotrites and accessory apparatus being figured. On the question of local *versus* general anæsthesia the author advises for obtaining insensibility of the bladder irrigation with 5 per cent. antipyrin, or 1 per cent. stovaine in quantities of 50 c.c. Dolbeau's perineal lithotripsy is described in a separate chapter; the mortality being the same as that of ordinary lithotrity, the author considers that it offers advantages in crushing large stones. A comparison is drawn between lithotrity, perineal and suprapubic lithotomy, and a table is given showing the relative mortality of each in the hands of continental operators. The average works out in favour of perineal lithotomy. Professor Schiavoni, without laying too much importance on these statistics, considers that they establish the superiority of perineal lithotomy, notwithstanding the difficulties of its technique and the danger of wounding vessels, and do not justify the present prevalent neglect and distrust of this operation. He maintains that the suprapubic method is preferable on the whole, but that this furnishes no adequate reason for banishing the perineal operation, which when well performed is eminently suitable for small calculi and for cases of chronic cystitis, and, moreover, can be followed by perineal lithotripsy which gives *the best results in unfavourable circumstances and has a* mortality less than that of lithotrity alone.

We have nothing but praise for the way in which the author has carried out this important work, while the type and woodcuts are admirable.

Monaco and Monte Carlo. By ADOLPHE SMITH. With eight reproductions in colours from drawings by CHARLES MARESCO PEARCE, and with 48 illustrations in black and white. London: Grant Richards Co. Philadelphia: J. B. Lippincott Co. 1912. Pp. 477. Price 15*s.* net.

To most people, including the small proportion of English who go there once or oftener in their lives, Monaco and Monte Carlo stand only for pleasure, and especially the form of pleasure that is typified by roulette and trente-et-quarante. It is well, therefore, that they should learn that the little Principality fosters interests of a beneficent character to a degree so out of proportion to its size. The larger nations, which affect to despise it as a "sink of iniquity," living by plundering its visitors, may feel somewhat shamefaced to know that in this small Principality more money, proportionately speaking, is spent on local government, on public works, on the promotion of original research, and on the arts and sciences, than is the case in any other part of the world. We have a right, all of us, to our views as to the way in which the money is got, but there cannot be two opinions as to the way it is spent. This more serious side of Monaco has recently been brought forward in Mr. Adolphe Smith's fascinating book, which covers the entire field of knowledge concerning the Principality of Monaco and the town of Monte Carlo Individual books and reports, it is true, dealing with the separate subjects of historical, archæological, artistic, and especially scientific interest, connected with or assiduously cultivated there, have been published, but these are essentially technical works intended for technical readers especially interested in the particular subjects and not for general reading. Mr. Adolphe Smith, we believe, is the first author to bring together within the compass of one book the historic, and even the prehistoric, data of this ancient Principality, the general and scientific characteristics and attainments of its present reigning prince, a bird's-eye view of the work in oceanography, anthropology, and archæology fostered and pursued by him in person and of the political and social economy of the Principality, its sanitary and industrial conditions, its cultivation of the fine arts, and its increasingly prominent place as the home of international congresses, as well as the one feature for which it has hitherto mainly stood in the world at large—viz., its facilities for gambling. The book is divided into two parts, the first of which deals with the historical, scientific, economic, and medical aspects of the Principality; the second is devoted to the subject of gambling generally, its development at spas, and its culmination at Monte Carlo.

The fortunes of the Grimaldis, to which ancient race Prince Albert, the reigning Prince of Monaco, belongs, form a romance that is fascinating reading to anyone with a taste for history. The politics and internal economy of the sovereignty, though it is so small a one, are not negligible, for this little state has served as a laboratory where practical legislative and other experiments have been and are being made, that serve as educational demonstrations for the benefit of many nations. With the principles and policy of a Prince, also, who, while inheriting upwards of seventeen hereditary titles and dignities, yet takes his greatest pride in those that mark the distinction he has won for himself in the realms of scientific investigation, we must needs be interested, and it is around *Albert of Monaco, Membre de l'Institut, that the* interest of the first part of the book mainly centres. A practical sailor, he has devoted the greater part of his industry to furthering the development of oceanography. It was he who established and endowed the Museum and Institute of Oceanography, the foundation stone of which was laid in Monaco on April 25th, 1899, and who later, in 1906, contributed to the University of Paris a sum which formed a considerable part of the capital required by it to purchase the land needed by the Sorbonne for its extension. In return the University granted him a site on part of the new estate on which was erected the Oceanographic Institute, founded by him and endowed with a working capital of 4,000,000 francs. This institute is devoted to the study of the geography, geology, hydrology, biology, zoology, and bacteriology of the sea; and to it has also been given the ownership of the before-mentioned Oceanographic Museum at Monaco, with its laboratories, collections, and aquariums. This institute is an autonomous and independent establishment in full possession of civil rights. In the museum at Monaco are stored the results of 24 different maritime explorations made by the Prince himself up to the beginning of 1912, and extending from Spitzbergen to Cape Verde Islands; and vertically upwards with balloons to a height of 43,400 feet, and downwards to a depth of 23,000 feet below the sea surface. The author describes with clearness and detail the treasures of the museum, as well as the anthropological and other scientific researches made and fostered by the Prince.

The portion of Mr. Smith's book that will undoubtedly interest medical men more directly is the chapter on Monaco, Medical and Sanitary. A discussion of its climate, drainage, slaughtering, water-supply, and hospital (described and illustrated by the author in THE LANCET[1] at the time of its inauguration) concludes the first part of the book. An powers of regeneration and compensation, though we see evidences of it constantly in practice, and Dr. Walsh enters an eloquent plea for the desirability of keeping the patient with chronic organic disease in just as good condition of body and favourable condition of mind as possible for a prolonged period. He emphasises the truth, with which every physician who has to deal with chronic cases is familiar, that these patients suffer from the serious burden of realising that their condition is incurable. But while nothing can be done for the disease itself, much, very much, can be done for the patient. If symptoms extraneous to the underlying disease can be assuaged, it will not surprise that the patient should think himself bettered; life will seem again to have something in it worth living for, and it would be hard to persuade him that some change has not come over his disease.

---

[1] THE LANCET, May 6th (p. 1229) and 20th (p. 1384), 1911.

No doubt these truths are, in a sense, a commonplace to the successful practitioner, but Dr. Walsh has a fresh and stimulating way of retelling them which we find very attractive. One of the most telling chapters in the book deals with the individual patient, and there are few who will not find helpful and instructive hints in these closely packed pages. An important element in diagnosis and treatment is detailed knowledge of the patient's ways and modes of thought. As Dr. Walsh says, every motive and every action of the day must be scrutinised; in fact, it is a good plan to begin with the getting up in the morning and to work steadily through the patient's doings during his waking life. Dr. Walsh's examination of these details is tempered with insight and a shrewd knowledge of human nature. But we are not sure that he has not allowed himself to be influenced by the accepted facts of the control of the mind over the bodily functions to such an extent that he occasionally minimises the genuine physical effect of a particular line of treatment. Thus: "For some years after the discovery of radium we were inclined to think that it must have some wonderful application in medicine and in surgery, and we actually secured many good results until its suggestive value wore off." This is not, we consider, a complete explanation of the facts. Dr. Walsh declares that at Lourdes "there is more than natural power manifest." In view of the fact that many hold a contrary opinion, the details of even one case, independently investigated under rigorous scientific conditions by a competent neurologist, such as Dr. Walsh, would be worth much more than a generalisation of this sort. Reference is made to the recent work of Dr. H. Head and Dr. G. M. Holmes on the optic thalamus, but we consider that Dr. Walsh's remark that they have shown "certain definite and very marked manifestations of *dualism of disposition* (italics our own) consequent upon lesions in the optic thalamus" attributes too much to their investigation and is rather a misreading of their position.

We can cordially recommend this book as a contribution to the subject of psychotherapy, one of the few which is characterised both by knowledge and by a due exercise of the critical faculty. Although it is a long book it is never dull or prosy: the aptness of the illustrations and a pleasant, readable style are calculated to appeal to student and practitioner alike.

Lehrbuch der Augenheilkunde in der Form klinischer Besprechungen. By Dr. PAUL RÖMER, Professor of Ophthalmology, Greifswald. Berlin and Vienna: Urban and Schwarzenberg. 1913. Pp. 380. Price 8 marks, or 9·60 kronen.

THE second edition of Römer's "Text-book of Ophthalmology" has followed the first, published in 1910, quickly. In the meantime we have had to review the first volume of the English translation. The opportunity has been taken in this edition of greatly improving the style and convenience of the book. It is now issued in two volumes. Much of the verbal diffuseness consequent upon the lecture form has been eliminated, so that it reads much more easily, and the size has been reduced by 200 pages without loss of any important material. Facility of reference has been increased by the excellent plan of marginal notes on the contents of the paragraphs. The general arrangement of the chapters is now more logical. The illustrations in the text now number 268, as compared with 186 in the first edition. Many have been reduced in size, some not without a certain loss of important detail. The coloured plates have been increased to 32, as compared with 13; they include figures of external diseases, ophthalmoscopic conditions, and microscopical specimens, and are for the most part very good. We have not noted any material change in the matter of the text. We can recommend the book warmly, especially as some of the defects to which we drew attention have now been removed.

Mind and its Disorders. A Text-book for Students and Practitioners. By W. H. B. STODDART, M.D. Lond., F.R.C.P. Lond. Second edition. London: H. K. Lewis. 1912. Pp. 518. Price 12*s.* 6*d.* net.

THIS is the second edition of Dr. Stoddart's work on insanity. Some alteration has apparently been found necessary in almost every chapter owing to the amount of research work that has been performed in the field of psychiatry since the first appearance of the book. The net result has not, perhaps, been large or at all striking except in the domain of morbid psychology. A chapter on the psychopathology of the Freudian school now appears, and shortly, though adequately, sets forth its outstanding concepts. Part I. of the work consists of a hundred pages of normal psychology, and, whilst interesting, largely serves to illustrate the slenderness of the tie between this subject and the practice of psychiatry. Part II. is devoted to the psychology of the insane, and is largely an account of the general symptomatology of insanity; while Part III. is concerned with the several groups of symptoms which it has been found convenient to separate and to name by various appellations.

The favourable general estimate which we formed in reviewing the first edition we can now with pleasure endorse.

Veterinary Toxicology. By G. D. LANDER, D.Sc., F.I.C., Professor of Chemistry and Toxicology in the Royal Veterinary College. With 39 illustrations. London: Baillière, Tindall, and Cox. 1912. Pp. 312. Price 7*s.* 6*d.* net.

FOR a long time there has been distinctly needed a work on toxicology dealing with the subject from a clinical standpoint as applied to the domesticated animals, and the veterinary expert of the present day owes a debt of gratitude to Professor Lander for the trouble he has taken to place this book before the profession.

All the common poisons are dealt with, being classified under the respective headings of mineral (inorganic), organic and drugs, and poisonous plants, the latter including several indigenous to South Africa. The arrangement deals with the causes, symptoms manifested, treatment, post-mortem appearances, and chemical diagnosis; and, considering the vast amount of literature which the author has had to wade through, the result is put not only clearly but briefly—sometimes rather too briefly. There is no doubt that when the book comes to a second edition much of the matter will be elaborated, especially the paragraphs which deal with symptoms and treatment. The veterinary practitioner has so many classes of patient, and so many different digestive systems to deal with, that generalised statements cannot possibly be made to fit all. Methods of treatment must be described in detail, for when applied, for example, to a dog, there are many observations to be made which would not be relevant in the case of a cow or horse In a book of this kind it is absolutely necessary to combine the experience of many practitioners with the results of laboratory work We think that on its issue there is certain to be an interest awakened in veterinary toxicology, and this will cause many specific details which are not in this present volume to be reported for publication in the future The work is needed and is good, but it would have been better had it not been so generalised, especially in regard to the sections upon symptoms and treatment, to which the practitioner will naturally turn first when in doubt

LIBRARY TABLE

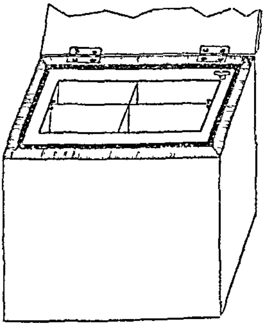
The Care of the Body By R S WOODWORTH, Professor of Psychology in Columbia University New York · The Macmillan Co 1912 Pp 359 Price 6*s* 6*d* net —We learn from the author's preface that "this book is intended chiefly for the young man, and is founded on the belief that an intelligent man, without technical knowledge of medicine, and without excessive attention to the care of his health, can still do much to keep himself in good condition " It is, therefore, a popular work on physiology, and as such can do widespread harm if it is not circumspectly as well as accurately written In the author's words, it "enters not too deeply into some of the important topics of physiology " On the whole, in our opinion, the book will prove useful to those for whom it is written, though occasionally Professor Woodworth, in his anxiety not to enter too deeply into physiology, has fallen into the opposite error, and writes in too superficial a manner Thus we think that the statement on p 76, that starch continues to be acted upon by the saliva in the stomach, is too positive a statement Its digestion is certainly delayed, and quite probably is arrested His first chapter, "The Science of Health," is eminently practical, and is an expansion of his remark on p 10, "If there is any one general rule which is useful in the care of health—call it principle, rather—it is to avoid excesses," but he is also careful to point out that what is moderate for one person may be excessive for another After the physiological chapters Professor Woodworth considers in a practical fashion such subjects as bodily heat, in which we are glad to see a word of warning against the foolish idea "that you should never wear an overcoat in the house, or you will not 'feel the good of it' when you go out " The proper use and care of the eye the ear, the muscles, the avoidance of causes leading to neurasthenia, and the judicious use of work, rest, and recreation are next dealt with, while in the three final chapters indulgences (e g , stimulants and tobacco), the cycle of life, and disease are considered In the last chapter we note that the credit for definitely proving that anthrax is due to the bacillus anthracis is given to Koch It is true that Koch was the first to work out the life history of the bacillus and to cultivate it outside the body, but we think that Davaine, who saw the bacillus in 1850, and in 1873 positively asserted that the "rods" were the cause of anthrax, should have been mentioned also

Guide to the Medical Schools and Teaching of Paris —This practical and illustrated guide is published for the modest sum of 50 centimes by Masson et Cie on behalf of *La Presse Médicale* There is a map of Paris attached, on which all the hospitals and schools that interest the medical profession are printed in red The date and place of the principal lectures for the year are given, as well as practical details concerning every class and laboratory available to the student, whether French or foreign We are reminded that not only are all the French clinics open to foreign medical men, but that there are in Paris clinics held in various foreign languages Thus we have the Anglo-American Medical Society with the Hertford British Hospital, founded by Sir Richard Wallace, 72, Rue de Villiers, and the American Hospital, 44, Rue Chauveau, Neuilly Then for the Latin languages, notably Spanish, there is *l'Union Médicale Franco-Ibero Américaine*, more briefly known as *l Umfia*, which has its headquarters at 18, Avenue Trudaine Medical men of the German language forgather at 120, Boulevard Saint Germain, and those of the Russian language at 4, Place Clichy All are welcome to profit by the medical teaching for which Paris has acquired world-wide renown This little guide gives us many details and pictures of the hospitals, laboratories, and institutions that are at the disposal of the medical student

New Inventions.

A PORTABLE RADIATOR FOR BLOOD CULTIVATIONS

IN cases of septicæmia in which a cultivation from the blood (basilic vein) must be made for the proof of a circulating organism there is a point in the technique which has not received the attention it deserves I refer to the desirability of keeping the broth tubes (inoculated at the bedside with the blood) at or nearly at blood heat from the moment of withdrawal until the incubator is reached This time in practice varies from a few minutes to several hours Human blood is bactericidal, and if in addition a big fall in the temperature occurs in the blood cultures an additional factor is allowed which is adverse to bacterial growth This defect in procedure was first pointed out to me some years ago by Dr H E B Bruce Porter, and reviewing the cultivations I have done under various conditions for the last seven years, in no case did I obtain so rapid or copious a growth of streptococci as in a case undertaken for him, and in that case the patient was lying a few yards from the incubator, and of course the time for cooling was very brief In the books one finds recommendations to carry one's tubes in wool warmed before a fire, or in one's coat pockets, or, again, a Thermos flask may be utilised Since the means of warming should be obtained in a rapid and simple way, I have designed and tested the appliance shown in the accompanying illustration The apparatus is a felt-lined wood case 8 by 8 by 4½ inches occupied by a metal container, divided into compartments by a sliding partition, and furnished with a buffer of wool or corrugated paper to prevent fracture of tubes on its metal floor The interior takes 16 tubes of culture media, and the box can be carried in a culture bag



The best test gave the following result By means of a funnel, one pint of boiling and a half pint of cold water were poured into the metal container and mixed The temperature of the experimental fluid (tap water) in the tubes was as follows 15 minutes after filling, 32 0° C , 30 minutes after filling, 34 5° , 60 minutes after filling, 37 5° (approximate blood heat), 90 minutes after filling, 35 2° , 2½ hours after filling, 31 0° By this simple and inexpensive instrument a temperature near blood heat (but not exceeding it) can be quickly secured by the use of boiling and cold water, which are always available when doing blood cultivations On arrival at the case I first proceed to fill the radiator, and after preparation of the arm the broth tubes are nearly at blood heat

THE LANCET.

LONDON: SATURDAY, MARCH 8, 1913.

The Position at the Royal National Hospital for Consumption for Ireland.

A MOST regrettable situation has gradually arisen in the affairs of the Royal National Hospital for Consumption for Ireland. Differences between the board of governors and the honorary medical officers have resulted in the resignation of the consulting and visiting medical staff. The institution is left without scientific direction. The Royal National Hospital is situated in county Wicklow, 22 miles from Dublin, and was opened in 1896 for the treatment of poor persons suffering from pulmonary tuberculosis in its incipient or early stages. During the 17 years of its existence excellent results have been obtained through its work; the open-air system of treatment was here given one of its earliest and fullest trials, and the work and size of the institution have gradually grown hand-in-hand with its success. But the Board of Management has gradually changed in character. Formerly in the 20 members some medical men were included, but these have dropped out one by one, and at present the affairs of the hospital are solely in the hands of laymen. The honorary medical staff consists of seven consulting physicians and two visiting physicians, together with an honorary consulting surgeon, who are all members of the staffs of different Dublin hospitals. The visiting physicians alternately visit the hospital each week and at other times when summoned by the resident medical officers, of whom there are two. The work of the visiting physicians has year after year received from the Board expressions of thanks and appreciation, and this was perhaps to be expected when the Board became entirely lay in its constitution, as it was clear that such a body would often be at a loss as to the rights and wrongs of a medical question, and dependent for advice as to the proper course to pursue upon their professional staff.

The circumstances leading up to the present crisis, however, show that the Board considers itself able to judge without medical interference upon important medical matters. The story is briefly as follows. In April, 1911, the two visiting physicians attended by request a meeting of the Board in order to express their views on a proposal to invite an outside medical man to try a special treatment for the relief or cure of tuberculosis at the hospital. The project did not commend itself to them or to the only member of the governing body present at the discussion. Six weeks later the board invited the consulting, visiting, and resident medical staffs to consider the desirability of adopting any special treatment at the hospital, including that which was proposed at the previous meeting. The whole medical staff thereupon expressed the unanimous opinion that medical treatment was a matter solely for the medical staff, and that in any case it was undesirable in the interests of the hospital that methods unproved by scientific research should be adopted. No action was then taken by the Board, but in December, 1912, the visiting physicians were informed by letter that the medical man previously referred to had been appointed as an additional physician to take charge, in particular, of insured patients. The reason given by the Board for this step was that owing to the expansion of the hospital the duties of the visiting physicians had outgrown their capacity and that additional help was needed. It may be mentioned here that the visiting physicians had expressed no desire to be relieved of any of their duties, which they had not found irksome in any respect. The visiting physicians accordingly conferred with the consulting medical staff, and jointly with them wrote to the Board expressing surprise at the appointment of an additional visiting physician without consultation with the existing medical staff.

And as in view of the circumstances summarised above the honorary medical officers could not avoid the belief that the new appointment had been made with a view to the adoption of methods of treatment which they had already disapproved of, they felt bound to resign their posts. In reply to their letter of resignation the Board expressed great regret, and earnestly asked the medical staff to reconsider their position. This the medical staff could not see their way to do, but they agreed subsequently to nominate four of their number to meet in conference with four members of the Board, in the hope of adjusting the difficulties which had arisen between the two parties. A friendly conference was held on Jan. 17th of this year, and draft terms of agreement were approved. Under these the medical staff agreed to withdraw their resignations subject to the adoption by the Board of a return to the *status quo ante*—i.e., before the appointment of the additional visiting physician—and a future representation on the Board of Management of at least two members elected annually by the consulting and visiting medical staff. The medical staff further agreed to approve, in the special circumstances which had arisen, the appointment of the medical man in question as pathologist to the hospital subject to the instructions of the visiting physicians. The reply of the Board to this proposal was that these terms could not be accepted, but that they again earnestly asked the medical staff to cancel their resignation. The position has, however, not been changed by this request, and on March 1st the entire honorary staff finally resigned their connexion with the hospital.

Thus the conflict of opinion between a lay board and a body of expert medical men upon what is essentially a professional rather than an administrative matter has deprived an excellent institution of the advice and assistance of Dr. WALLACE BEATTY, Dr. MICHAEL F. COX, Dr. J. MAGEE FINNY, Sir JOHN W. MOORE, Dr. JOSEPH O'CARROLL, and Sir WILLIAM J. THOMSON, the consulting physicians, of Mr. W. I. DE COURCY WHEELER, consulting surgeon, and of Dr. ALFRED R. PARSONS and Dr. JAMES B. COLEMAN, the visiting physicians. This loss by itself would be a severe blow to the hospital, but the matter is far more serious than that. Unless the board of governors can set itself right with the medical profession the whole future of the institution is in jeopardy. The resigning medical men have already issued a circular letter to the medical profession in Dublin and neighbourhood, setting forth the history of the dispute and their reasons for the step they have taken. Their object in issuing this statement to their colleagues is to make them "aware of the conditions under which any persons now to be appointed to the medical staff must hold their positions." The correspondence and various statements which we have had before us lead almost irresistibly to the conclusion that the lay board of the Royal National Hospital for Consumption for Ireland has brought this trouble upon its own head, and that no medical staff could in justice to itself, to its profession, and to its patients have acted otherwise.

The Problem of Medical Practice in India.

In another column (p. 707) our readers will find a detailed consideration of the present position of the medical profession in India from a correspondent who is intimately acquainted with the facts. The multifarious duties carried out by the officers of the Indian Medical Service in its various branches are clearly set forth, as well as the more important conditions under which the work is conducted, and the relations that subsist between this service and the rest of the profession in India. The conclusion arrived at is that, on the whole, the medical provision of the country is efficient and satisfactory, and that from the point of view of the State, as concerned with the health and medical care of the population, no considerable change is required. As regards the interests of the medical profession there are two points of view—that of the Indian Medical Service and that of the body of independent medical practitioners. The latter feel a grievance at the extensive monopoly of lucrative posts held by the former. The former naturally object to any curtailment of the position, privileges, and emoluments, on the faith of obtaining which they have entered the service and devoted their energies to a life's work in India. Our correspondent takes the view that the honourable conditions of service in the Indian army, together with good pay and prospects, and ample leave, would be sufficient to maintain the Indian Medical Service at its present high level of efficiency, and that the liberty of private practice might be withdrawn without injuring that distinguished service and with advantage to the medical profession and India generally. He considers also that the professional appointments in the presidency towns should be held by civilian medical men, and not attached, as at present, to some particular civil appointment of the Indian Medical Service.

Our correspondent is probably fully aware—as we ourselves are aware—that such sentiments will be painful to some members of the Indian Medical Service, but other members of that service who have given close attention to a very difficult subject and have accordingly realised the increasing responsibilities of their select body, have already seen that considerable modifications in the present conditions of medical practice in India are desirable, and indeed inevitable. It must be admitted that many officers of the Indian Medical Service are overworked, having more numerous and more varied duties than they can possibly perform satisfactorily; there is no need to give specific instances, they can be found in the official directories. There has been too much concentration of duties, executive, professional, professorial, in too few hands. There are other matters also of administration, such as too frequent changes of station among the junior officers, which need, and doubtless are receiving, the attention of the authorities. But what we feel ought to be regarded as of the chief importance is the maintenance of the existing high standard in the *personnel* of the Indian Medical Service. In saying this we do not mean that the interests of this branch of the public service should be preferred to those of the public service in general; or of the inhabitants of India, whether native or European; or of India itself the country and the people. We feel convinced that there need be no conflict between these interests. The record of the British rule in India is one of which any nation might be proud, and the medical profession has had its full share in this record. "Peace hath her victories no less renowned than war"; the Indian Medical Service has borne a distinguished part in both. More than any other branch of the public service, the men of the medical department have reconciled the people of India to a foreign government. "The influence of the European physician upon the native races of India has been of an importance, not only great in itself, but great in a proportion probably far exceeding any other; and I venture to think that, if at any time our *raj* in the country came to an end, the influence that would be longest remembered and bear most lengthy fruit would be that exercised by our profession." These are the words of DE CHAUMONT, spoken in 1881, and it is the aspiration of the whole of the medical profession that they should remain true, and that the progress of India should go hand in hand with medical progress.

At the present time the members of the Indian Medical Service are actively engaged in every branch of professional work and scientific research. It would be invidious to mention names, many of which are known throughout Europe as pioneers in all branches of medical, surgical, and sanitary science. Besides these there are very many other workers whose names are not known to fame, but who are spending their lives in the hardest toil in remote parts of India, often in complete isolation professionally, and with hardly any European comrade. The daily work and responsibility of these men are increasing and unceasing. They make up the main body of the Indian Medical Service. We should look with the greatest regret on any change in the position and prospects of the service which would in any way injuriously affect the status and interests of these members of the profession, or which would in any way deter men of the like high character and attainments from entering the Indian Service, a service which has hitherto attracted some of the best men sent forth from our medical schools, whose subsequent achievements have been an honour to our race. But when the necessity for change arrives it is imperative to be ready to take full advantage of the new order of things. The Indian Medical Service is not befriended only by those who praise its past achievements. It has equally sincere admirers who desire it to be prepared for developments so that the value of these developments may be attended with a minimum of sacrifice. From which it may be seen that we cannot go all the way with our correspondent, but consider none the less that he has raised questions which will have to be faced in the near future.

The Ambulance Supply of London.

WE recently referred, in commenting upon an inquest held at the City of London coroner's court in January last, to the acute need for ambulances to supply, at any rate, the street and emergency needs of the metropolis. In the case in question it may be remembered that the deceased was taken ill suddenly at the Islington Empire Theatre and was conveyed on an ambulance to St. Bartholomew's Hospital, where he died. More than half an hour elapsed before he was transported where he could receive medical attention. Dr. F. J. WALDO, the coroner for the City, in commenting upon the circumstances of the case, expressed his desire that the London County Council should go into the matter and provide ambulances, mentioning at the same time a common apprehension lest the numerous and various functions of the Council should already over-occupy its time. Some discussion on the question of ambulance service for the County of London took place at the meeting of the London County Council on Feb. 18th, when this very case was under discussion.[1]

The history of the efforts which have been made in the past to provide London with an efficient service is not without interest, and is, indeed, illustrative of the difficulties that always attend any movement which is made to provide a new administration for London, owing to the division of the county services among various authorities who separately undertake branches of work elsewhere devolving upon the one municipal authority responsible for all. London has up to the present time had practically to depend for the removal to hospital of persons meeting with accidents in the streets upon the provision of hand litters kept at various police stations, upon the use of hand litters provided by the Bischoffsheim Ambulance Service, and upon ambulance litters and stretchers provided by the St. John Ambulance Association. There is no uniform or coördinated service which can be depended upon for the prompt removal from all parts of the metropolis of injured persons. The London County Council in 1906 applied to Parliament for powers to establish a much-needed ambulance service, and the evidence given before a Committee of the Houses of Lords and Commons showed the kind of vehicles, often cabs and barrows, which conveyed to hospital persons suffering from serious injuries. The use of these rough conveyances added to the probability that simple fractures would become compound in the act of removal to hospital. The London County Council was then prepared to establish an efficient service by which motor ambulances could be fetched by the use of telephones established in the streets throughout the metropolis. The estimate of the cost was by no means excessive, and the House of Commons was ready to confer the necessary powers on the Council. The City Corporation opposed the Council's Bill, having provided an excellent service in its own area while the subject was under the Council's consideration. In the House of Lords the Council was less fortunate, and for one or another reason its proposals were rejected. The pressing need for the subject to be dealt with in an adequate and comprehensive manner was, however, generally recognised, and it was obvious the matter could not remain in so unsatisfactory a position. Hence the Home Secretary, then Mr. H. J. GLADSTONE, appointed a Departmental Committee which, after hearing evidence, came to the conclusion that such a service as the County Council had proposed was a real necessity, but recommended that its provision should be entrusted to the Metropolitan Asylums Board. There was then some justification for this conclusion, inasmuch as the Managers of that Board had provided an excellent service for the removal of cases of infectious disease from the homes of the patients to the various fever hospitals, and the London County Council had at that time no touch with the subject of ambulance provision. A Bill, however, was introduced into Parliament by Sir WILLIAM COLLINS which gave the Council all the powers it needed, but a change in the constitution of the Council led to the exercise of these powers remaining in abeyance.

Since the recommendations of the Departmental Committee of the Home Office were arrived at the position of the Council has been materially altered. It now possesses an ambulance service for the removal of defective children to the special schools, while a large development of this service is inevitable if economy is to be effected in the provision which is being made for the medical treatment of children attending the ordinary schools. Obviously the treatment centres must be multiplied or facilities given for the conveyance of the children to a smaller number of more distant treatment centres for the purposes of medical attention. It is now proposed to apply to Parliament for powers to enable the County Council, the Metropolitan Asylums Board, and the boards of guardians to enter into agreements for the use for the purpose of any ambulance service which may be established under the Metropolitan Ambulances Act of 1909 of the premises and ambulance appliances of these authorities. This is at the best to provide London with a patchwork service which is not likely to prove efficient. It will fail in the one necessity that the whole service should be vested in one authority, and this is a side of the question which the County Council would do well to consider.

DEVON AND EXETER DENTAL HOSPITAL.—At the annual meeting of the subscribers to the Devon and Exeter Dental Hospital, the medical report stated that during 1912 the patients attended numbered 2543, making a total of 141,731 since the institution was founded. The financial statement was satisfactory. The committee announces that a new scheme has been introduced in the past three months of providing, at an extremely low cost, artificial teeth for those among the poorer classes who were in need of them.

Annotations.

"Ne quid nimis."

THE DOMINANT NUISANCE OF MODERN CIVILISATION.

IN a recent case in the Chancery Division, in which Mr. Justice Swinfen Eady was invited to restrain the keeper of a fried fish shop from continuing the nuisance alleged by his neighbours to arise out of his trade, his lordship granted an injunction, and cited as the authority for his own guidance in so doing a definition of a nuisance laid down by Sir James Knight Bruce. That learned Vice-Chancellor, whose language has been described by a biographer as always terse and lucid, defined a nuisance with which the Court of Chancery might interfere as "an inconvenience more than fanciful, and more than one of mere delicacy and fastidiousness, an inconvenience materially interfering with the ordinary comfort, physically, of human existence not merely according to elegant or delicate modes and habits of living, but according to plain and sober and simple notions among English people." Sir James Knight Bruce was promoted to the Bench in the Court of Chancery by Sir Robert Peel in 1841, and died in 1866. The exhalations of a fried fish shop are probably more familiar to those who now live in or traverse the humble streets of the metropolis than they were to him and to his contemporaries, owing to modern conditions of transport and storage, but in most respects a more sanitary and less malodorous London affords a home to a vaster population, and similarly improved conditions are to be found in provincial cities and country towns. If, however, the Vice-Chancellor, revisiting the scene of his judicial labours, might observe an increase in "elegant or delicate modes and habits of living" among us we venture to suggest that he would be struck at the same time with the increase of a particular form of nuisance, and with the tolerance extended to it. We refer to the nuisance of noise. The "roar" of the traffic of London was no doubt considered remarkable in the middle of the nineteenth century by those who frequented its more crowded streets, paved with granite and used by vehicles all of which had iron tyres, but it is not to any increase of noise in busy localities that we refer. Horseless traffic by introducing the horn has in the last few years brought sudden nerve-distracting noise into the quietest thoroughfares at all times of day and night, while there come also heavy vehicles of the traction engine type, apparently subject to no restriction of any value to the sleepless citizen. The horsed omnibus has, of course, been replaced by the motor omnibus, and we hardly need mention the growing numbers of these vehicles or their introduction into streets where public conveyances were formerly unknown. Street bands may be fewer, and perhaps the demands of modern traffic for free use of the roadway are responsible for this, but, on the other hand, the hurdy-gurdy against which our fathers inveighed has as its substitute the far noisier piano organ. Of the date of the introduction of the cab whistle we are not aware, but few will deny its more frequent use during recent years and an appreciable increase in the volume of sound produced by it. Such nuisances as arise directly out of noisy trades, out of the proximity of skating rinks, and out of efforts to attract audiences to picture palaces are proceeded against by neighbours, though often at a considerable cost to themselves. The nuisance of noisy traffic concerns citizens in general, and if some "plain and sober" persons may not object to it, we have little doubt that the great majority desire to see it abated. The muffin bell and the cries of the street-hawker have been largely suppressed, not so much by the making and enforcing of by-laws as by a change in our habits, and it does not seem unreasonable to suggest that an attempt might be made to deal also with the cab whistle and the motor horn. The former is, of course, cheaper in use than electrical communication with the nearest cab rank, and a substitute for it as a means of summoning the "crawler" is not easy to devise. The motor horn is used to facilitate fast driving and as a substitute for slowing at crossings, which had to be done by the less insistent method of horse traffic. At present a house situated near a busy street corner is inhabited subject to gross nuisance, for by day and night every private car or taxi-cab that passes it in proceeding towards the corner hoots two or three times in doing so. Cars approaching the cross roads from other directions hoot at a slightly greater distance. All this would seem to suggest a combination of the dwellers in such houses, for the protection of the value of their own property and of their own comfort; they should demand the enforcement of careful driving, and the forbidding of hooting in the circumstances described. A very large proportion of the population of London must suffer in health and temper from interrupted rest at night, and by day from the lack of reasonable quiet in their places of business and in their homes. We do not forget, when we compare the traffic in London to-day with that prevailing in the middle of the last century, that in those days there was neither wood pavement nor rubber tyres, and that the clatter of horses' hoofs has almost ceased. These considerations, however, suggest that if we took full advantage of modern developments our streets might be rendered far more quiet, a consummation which our descendants may arrive at, but which at present we are far from attaining.

THE DEATHS OF THE KINGS OF ENGLAND.

THE deaths of kings have always held a foremost place of interest in the minds of men, so much so that, to speak paradoxically, tradition tells us that more than one king's death is really a resting life. Arthur of Britain sleeps in the isle of Avilon, Charlemagne slumbers until the times of Antichrist be fulfilled, Barbarossa with six of his knights rests in the Kyffhauserberg until Germany shall have need of his aid, as, in like manner, with reference to their own kingdoms, do Ogier the Dane and Olaf Tryggvason of Norway, while even so modern a sovereign as Napoleon Buonaparte is believed to be awaiting his country's call. The life of a monarch has at no date been an easy life; in earlier times he was a mark for the assassin and the enemy, and in all ages a really conscientious ruler is weighed down by the burden of responsibility. In England eight sovereigns since the Conquest have been done to death or slain in battle. In Scotland and Ireland we make no attempt to summarise the bloody tale. It is small wonder that Shakespeare made Richard II., as if in premonition of his own miserable death, "tell sad stories of the deaths of kings." But the study of diseases from which kings have died, if carefully conducted, is capable of throwing light upon the medicine of history, and so by direct conversion upon the history of medicine. The latest work on the subject is a monograph by Dr. James Rae[1] entitled "The Deaths of the Kings of England." Dr. Rae in his preface refers to previous writers on the matter, who are very few in number. Sir Henry Halford gave a lecture in 1819 on Deaths of Eminent Persons, Dr. Raymond Crawfurd in 1909 published an interesting monograph on the death of Charles II., and a series of articles appeared in the *British*

---

[1] The Deaths of the Kings of England. By James Rae, M.A., M.D. London and Manchester: Sherratt and Hughes. 1913. Pp. 152. Price 4s. 6d. net.

Medical Journal, 1910-11, under the heading Some Royal Death Beds. Dr. Rae takes the sovereigns of England from William I. to William IV. and has carefully collated the authorities who have given accounts of the deaths of the various monarchs. On the information thus collected he founds his diagnoses. He himself admits that some of his diagnoses "may be considered fanciful," and herein we agree with him, but all the same his theories are of interest, and in one case only does he seem to us to attribute death to a cause which lacks plausible arguments in its favour—namely, the case of Henry II., whose "fever" he considers to have been a dysenteric affection. One daring diagnosis is of interest in these days of hunger strikes—that Richard II. died from anorexia nervosa. The chronicle says, "semetipsum inedia voluit peremisse," and also that when on the advice of his friends he gave way and tried to eat, "all appetite was gone and the opening of his stomach had closed up so that he died." This account, says Dr. Rae, is quite consistent with a diagnosis of anorexia nervosa. Richard may well have become unbalanced mentally; he was but a child when he came to the throne, and the political state of the kingdom was enough to try the strongest brain and will. Everyone will not agree with all Dr. Rae's diagnoses, but we can thank him for an entertaining book, the value of which is increased by the excellent bibliography.

OVARIAN INFLAMMATION COMPLICATING EPIDEMIC PAROTITIS.

Professor Harlow Brooks of New York calls attention to the fact that ovaritis does seem to occur occasionally as a complication of mumps, albeit in a very small percentage of cases. If the frequency with which the testicles are involved be held to have any bearing on the probability of ovarian inflammation, it seems not unreasonable to attribute the pelvic symptoms noted in this writer's two patients to true ovaritis, though apparently so far no one has actually seen an inflamed ovary in connexion with unquestioned mumps. In a certain number of the cases which have been recorded as instances of ovarian mumps the evidence put forward is not convincing; many of these are disqualified by the youthfulness of the patient, which makes an adequate pelvic examination impracticable. Both of Professor Brooks's patients, however, were grown women. In the first of the two cases which he reports in the *Journal of the American Medical Association* of Feb. 1st the patient was a healthy multipara, aged 28. The parotitis, which was limited to the left side, was followed after a week by pain in the region of the left ovary, which became enlarged and very tender. After two days the pain diminished; this was followed by a menstrual period which occurred ten days before it was due, and was more profuse than usual. After this the ovary, though still painful and enlarged, was much less so. During five years following this attack the patient did not become pregnant; after that time she was lost sight of. In the second instance, that of a married multipara 24 years of age, the pelvic symptoms appeared, together with a rise of temperature, five days after the onset of a mild attack of bilateral parotitis. Both ovaries became enlarged, each to the size of a hen's egg, and extremely tender and painful. Two days later both breasts became acutely inflamed, but the patient was quite well a month later. Since then she has been under periodical observation for six years. Her periods have been regular and normal, and though she has not become pregnant, this is probably due to the fact that her husband is syphilitic. It is worthy of note that the breasts, which formerly presented a normal firmness and bulk, have become atrophic and flabby. In both cases it is reasonable to assume that the micro-organism, or whatever it is that irritates the salivary glands in mumps, provoked a similar reaction in the ovaries, to which it had been carried by the blood-stream. In the whole range of pathology there is no more striking example than mumps of the predilection manifested by certain micro-organisms for attacking certain types of tissue; for it can hardly be doubted that mumps is a bacterial infection. When pathologists have leisure to turn from the investigation of the graver infections to a search for the exciting cause of epidemic parotitis, it is possible that their quest will be rewarded by the discovery of facts which are of importance for the whole pathology of infective disease.

FEBRUARY AT HOME AND ABROAD.

FEBRUARY was appreciably colder than January, both in this country and on the continent, and it was also much drier and generally much more sunny. In England the average afternoon was from 3° to 5° colder, and the nights about 4° colder. The month, however, was not cold for the time of year, the temperature as a whole scarcely diverging at all from the average for the past 30 years. The rainfall, on the other hand, differed considerably from the normal. February has about the smallest average of the year, but last month was much drier than usual, a large area getting only about half the normal quantity of rain, and many localities only about a third. But although so dry the weather was not correspondingly bright. In many places the total number of hours of sunshine was far below the average, and in few above it, and the number of sunless days was high. In the London area, as represented by Kew observatory, the mean maximum temperature was 46° and the mean minimum 35°, figures almost identical with the February average. At Nottingham the mean maximum was also 46°, but the minimum was 33½°, while at Bath the mean maximum was as high as 48° and the mean minimum 34°. The extreme south-west coast of England did not escape the lower temperature, but it was still warmer than the other parts of the country. At Newquay the mean maximum was a degree lower than that at Bath, but the mean temperature of the nights was 4° higher, and at Scilly, where the mean maximum was 49°, the mean minimum was no lower than 41°. The Channel Islands differed little from Scilly; at Jersey the mean afternoon maximum was 49° and the mean minimum 40°. There was, in spite of the rather low average level of the thermometer, very little severe frost in any part of the kingdom. In London the thermometer sank below 32° on only eight nights, the lowest point reached at Kew being 27°, while at Nottingham and Bath the corresponding figures were 12 and 13 respectively. At Bath the greatest cold was 28°, and at Nottingham 23°. In London the temperature reached or exceeded 50° on nine days, but in January the same figure was reached or exceeded on 19 days. At the Scilly Isles and Jersey there was no actual frost, but at both places the thermometer just touched 32° on the night of the 18th–19th. Sunless days were nearly as frequent as during January. At Kew there were as many as 12 on which the sun was not visible at all or shone so feebly that no record was burnt on the recording card, and the total number of hours for the month was no greater than 37, a figure 23 hours below the February average, and just equal to the average for January. The metropolis, however, experienced occasional fog and mist, which were much less prevalent over the country generally, and some of the cities of the Midlands recorded several hours' more sunshine. At Nottingham there were 41 hours, against an average of 50, and at Bath there were as many as 71 hours, against an average of 63. In the far south-west the figure was near the normal. At Newquay there was the very good total of 94 hours, at Scilly 80 hours, and at Jersey as many as 109 hours. This last value is 17 hours in excess of the normal. Rain and snow were seldom experienced. Both at Kew and Newquay there were no more than 10 days with rain, and at the humid Scilly Isles only 12, while at Jersey the figure was as low as 7. The continent was drier still. At Paris and Nice there was rain on only 4 days, and snow or rain fell at Berlin on only 5 days, and Biarritz sometimes so rainy in February, had rain on no more than 9 days. At Paris the month was remarkable for the sunshine. Although there were 6 days entirely sunless, the total for the month was as high as 150 hours, giving the very high daily mean of 5 hours and about 20 minutes. In London the mean was about four hours less. Owing to the sunshine Paris was milder during the daytime than London, its mean maximum temperature being 48°. At night, however, it was colder, having a mean minimum of 32° and frost on 16 occasions. Berlin was not cold for February, but its temperature was much lower than at Paris or in any part of England. Frost occurred on every night after the 13th, and about the middle of the month continued throughout the day also. The mean maximum temperature was 42° and the mean minimum 29°. The Riviera had a brief touch of cold from the 18th until the 20th, when snow showers fell locally and the thermometer at night fell to the freezing point, but as a whole the month was mild and very fine. At Nice the mean maximum was 4° above that at Scilly and Jersey, but the mean minimum was a little lower, the figure being 38°, just the same as at Newquay. Biarritz was not so consistently bright as the Riviera, but was mostly very fine, and its temperature was rather higher than at Nice both during the day and night. Frost occurred on three nights, and the mean minimum temperature was a degree lower than at the Scilly Isles. Madeira, although beyond the direct influence of the weather systems of Europe, was also colder than during January. Its mean maximum temperature was 64·4°, against 65·5° in January. The mean minimum however, was practically the same during the two months—in round figures 48°. There were only seven days with rain, and on most occasions the fall was slight.

THE ENDOWMENT OF RESEARCH

IN the interesting inaugural lecture delivered by Professor J. M. Beattie on his assumption of the duties of the chair of bacteriology in the University of Liverpool he spoke of the triumphs already won by that science and of its aim—the prevention of disease—and of the methods by which that aim should be attained. He is struck by the danger which arises from specialisation, from the separation of the bacteriologist from the pathologist and of both from the practical physician or sanitarian. This danger, he thinks, can be met, and is being met, by such cooperation of investigators as has been realised for many years in the laboratories of the continent and for some time in America, where, according to Professor Beattie, it attains its highest ideal in the Rockefeller Institute. If "cooperant, and not specially individual, work is the keynote of success," and if, as experience has shown, it is by the close coöperation of fellow-workers in an institute that this success can be realised, how does England stand in this respect and where are our institutes? Professor Beattie is able to point to one, and one only, in the British Isles—the privately endowed Lister Institute. On the basis of the past record of bacteriology, a record which shows results capable of being expressed in terms of financial profit, he claims increased help in the future. Is there prospect of such help? Under the Insurance Act a fund for the endowment of research in tuberculosis is provided, and the suggested schemes for its use include the provision of a central institute such as Professor Beattie desires, or the assistance and completion of the fairly numerous existing centres which with further financial aid could easily attain to his ideal of scientific coöperation. Unfortunately, the attempted treatment and prevention of tuberculosis will more than exhaust the funds available under the Act, and Insurance Committees are already appealing to the Treasury for further aid, so that this source of help may not be realised for some time. There is, however, a change of attitude and a greater sympathy shown by the Government towards educational grants, but there is grave reason to fear that these grants are given from a desire to secure control rather than from any desire to assist education, and it behoves educational authorities to try to educate the Government in the proper principles of administration of such grants. That the man who pays the piper should call the tune is admitted, but if the paymaster is devoid of an ear for music and attempts to teach the orchestra how to play the tune he has called, the result is cacophony. There is no doubt as to the object—practically the avowed object—of the grants made to certain London medical schools, and it is against interference by the Treasury with their educational aims that the Scotch universities have had lately to make vigorous protest. It is for strong bodies like the universities to see that Government grants are not given under such conditions as to render them dangerous rather than helpful.

THE "PARISH DOCTOR" IN SPAIN

ACCORDING to *La Cronica Medica* of Valencia the students and alumni of that university have been meeting in protest against the unsatisfactory way in which parish doctors are paid—or not paid—by the communal authorities, a case being mentioned in which one unfortunate medical officer had not received his nominal salary of £40 for 22 years. The Madrid students are also joining in the agitation, as was pointed out last month in these columns by a Spanish correspondent. The object is principally to get the local medical and educational services put directly under the central government, so that the medical officers and schoolmasters should not be entirely under the thumb of the local authorities.

DEMINERALISATION IN HYDRO-THERAPEUTICS

AN interesting note in which the therapeutic claims of Evian Cachat water are briefly and clinically explained by Dr. Paul Bergouignan has reached us, the principle upon which the treatment is founded being that of demineralisation. With this end in view the most valuable ally is, of course, a coöperative *régime* in regard to diet, for it is obviously useless to try to demineralise tissues which are in constant process of being over mineralised. Demineralisation, primarily a dissolving and flushing process, as evidenced in a course of Evian Cachat waters, relieves the body of waste matters out of the blood, the liver, and other organs, and excretes them through the kidneys. The water is admittedly not radioactive, while chemically it contains practically no salts of clinical importance. According to our own analysis made in 1902 the total solids only amounted to 3 grains per pint, consisting chiefly of alkaline carbonates and a very small quantity of sodium chloride. Clinical observations have shown that the urine after the water has been administered fasting contains twice as much uric acid and five or six times the quantity of chlorides as the urine voided during the preceding night. The bottled water retains much of its diuretic power, and experiments at some of the hospitals in Paris show it to be more active than distilled water and three times as diuretic as that supplied through the city mains. The diuretic activity is best secured when the patient is directed to maintain the recumbent posture for two hours after the last dose. Any disease of the kidneys which seriously impairs their excretory capacity may be regarded as a definite contraindication to the Evian treatment. In the case of neurasthenics who owe their "rather vague but very trying subjective symptoms to auto-intoxication" the demineralising power of the waters is described to be seen at its best, but, of course, the general happy condition of the place, the climate, the scenery, the air, and even the colour, lend very powerful aid to the cure. If it is admissible to speak of the pharmacology of this water, it is probable that we are dealing with physical agencies, amongst which must be counted osmosis.

DR. WILLIAM BEAUMONT.

A LITTLE more than one hundred years ago—namely, on June 9th, 1812—a licence was granted to William Beaumont, by the Third Medical Society of the State of Vermont, to practise physic and surgery, and ten years later occurred that tide in his affairs which, taken at the flood, led him to fame, if not to fortune, for it was then that he came into contact with Alexis St. Martin, and began to conduct the physiological research which practically laid the foundations of our knowledge of the physiology of digestion. Although several cases of gastric fistula had been reported before Beaumont's day, yet in none of these, except one, do we find that any experiments upon digestion were made. The earliest deliberate experiment upon digestion which we can call to mind was made by the Emperor Frederic II., *circa* 1240, who, as recorded in Salimbene's Chronicle, fed two men at dinner. One of these was then sent to sleep and the other to hunt. In the evening the two men were disembowelled, as the Emperor wished to know which of the two had digested the better, and the physicians gave a verdict in favour of him who had slept. Another and even worse instance is on record of some sixteenth century Calvinists in the Low Countries. Having seized an aged Catholic priest they roasted his legs before a fire and, cutting off the cooked portions, made him eat them. Then, wishing to see how digestion progressed, they cut open his stomach, so that he died. Such experiments, however, can scarcely be called scientific, and it is Beaumont's glory that with very imperfect apparatus, and under most adverse circumstances, he was able to make such sound observations as he did, and to keep such admirable records thereof. An interesting study of Beaumont's life has been recently published by Dr. Jesse S. Myer, of St. Louis.[1] From this we learn that William Beaumont was born on Nov. 21st, 1785, being the third son of Samuel Beaumont, a farmer, of Lebanon, Connecticut. He attended the village school and worked on his father's farm until he was 21, when he left home to seek his fortune. In the spring of 1807 he arrived at Champlain in the State of New York, close to the Canadian frontier, and after finding employment as a schoolmaster determined to study medicine. With this object in 1810 he went to St. Albans, Vermont, where he bound himself apprentice to Dr. Benjamin Chandler, who seems to have been a most admirable teacher. Beaumont's case-books kept by him during this period show that he soon began to be an excellent observer. In June, 1812, he received his licence to practise, and on the declaration of war with Great Britain he applied for and obtained a post as surgeon's mate in the army, his commission being dated Dec. 2nd. In March, 1813, his regiment was sent to Sackett's Harbour on Lake Ontario, and on his arrival there he wrote to Dr. Chandler giving sundry military details varied with medical matters, such as: "The old Brunonian practice, a little varied and changed into the Chandlerian, succeeds almost to a miracle." He adds with a laconic brevity which would have endeared him to the heart of "brave Broke" of Shannon fame: "Yesterday we shot a soldier of the marine corps for desertion; we could not obtain the privilege of dissecting him. Next Thursday another is to be shot." Beaumont was present at the battle of Little York, April 27th, 1813, at which he noted with disapproval the "inhuman project" of the British in blowing up their magazine, and at the battle of Plattsburgh, August, 1814. In June, 1815, peace having been concluded, he resigned from the service and started in private practice in Plattsburgh, combining professional work with the keeping of a store for "drugs, medicines, groceries, dye woods, &c.," the &c. including such articles as "segars, gin, snuff, plug and paper tobacco." In March, 1820, he re-entered the army, and was sent to Fort Mackinac on Lake Huron. In 1821 he married Mrs. Deborah Platt, and in 1822 came to the turning point of his professional life. On June 6th of that year a number of Canadian voyageurs were in the store of the American Fur Company at Mackinac, and by the accidental discharge of a shot gun Alexis St. Martin was wounded in the abdomen. The gun was so close that St. Martin's clothes were set on fire, and the charge, duck shot, was practically solid. The wound was on the left side, and opened both the thoracic and the abdominal cavities. Sundry ribs were fractured, one of which tore away a portion of the wall of the stomach, and a large part of the left lung came out of the wound. In addition, the tissues were full of shot, bits of cloth, and fragments of bones and cartilage. Beaumont's description of the wound and his treatment is very full and extraordinarily interesting. A good deal of the lung sloughed, but the patient's recovery though slow was uninterrupted. It was then that Beaumont began that masterly series of experiments which were continued at intervals for some 11 years. The results of these investigations were published by F. P. Allen, Plattsburgh, in 1833, the title of the book being "Experiments and Observations on the Gastric Juice and Physiology of Digestion." From his Government Beaumont received the consideration which Governments commonly show towards scientific investigators, that is to say, indifference. In 1840 he retired from the army and took a country place near St. Louis. He died on April 25th, 1853. The medical profession owes a debt of gratitude to Dr. Myer for his careful and sympathetic study of one of the pioneers in medical physiology.

INCLUSION BODIES IN SCARLET FEVER.

ANY method which renders an early and definite diagnosis of scarlet fever possible would be welcome as a means by which the number of so-called relapses and second attacks might be diminished. The inclusion bodies, first described by Döhle, seemed to offer possibilities in this direction, and have been officially accepted by the City Health Department of Boston as of diagnostic value. An inquiry into their importance and significance has been recently made by Dr. John Granger and Dr. C. Kingsley Pole, and will be found in the *British Journal of Children's Diseases* for January, 1913. These cell inclusion bodies are regarded by Döhle as representing the fragments of a spirochæta which has been partially disintegrated, but as the bodies occur in many other diseases than scarlet fever there can hardly be any suggestion of their etiological importance in the disease. They were found by Dr. Granger and Dr. Pole in a large proportion of cases of diphtheria, measles, and tonsillitis, and, indeed, in most cases caused by ordinary pyogenic organisms, especially if streptococci were present, though they are absent from the blood in toxic rashes. These observers found the inclusion bodies in practically every case of scarlet fever during the first four days of illness, but their results, as indicated above, show that it is impossible to diagnose scarlet fever by blood film examination alone, though the absence of the inclusion bodies practically excludes that disease.

TREATMENT OF BURNS BY THE APPLICATION OF ALCOHOL.

In the *Australian Medical Journal* of Jan. 4th Dr. E. T. C. Milligan has described a method of treating burns which he has found more satisfactory than the current methods. In burns of the second, third, and fourth degree cleansing with antiseptic lotions is usually recommended. The moisture causes the sloughs to become septic—in other words, converts dry into moist gangrene. Frequent and painful dressings are then necessary. Dr. Milligan excludes water from the treatment and applies alcohol. He thus prevents moist gangrene and inflammation and saves much suffering. A child, instead of spending several months in hospital, can soon have the burn grafted and run about. The details of the method are as follows. If the patient is in such a state of shock that he cannot stand an anæsthetic, a watery saturated solution of picric acid is applied on lint and protective is put over this to prevent evaporation. On the next day the protective is lifted and more of the solution is poured over the lint, which is not changed. On the third day the patient is either obviously going to die or can stand an anæsthetic. If the picric acid be continued any longer the burn will become offensive. Dr. Milligan has not found the picric acid treatment of burns satisfactory, and simply uses it in the absence of anything better for a patient in condition of shock. Moreover, the acid is absorbed and may cause toxic symptoms. If the patient is in a condition to allow the administration of an anæsthetic he is given chloroform and the burns are cleansed with sterile gauze wrung out of 70 per cent. alcohol. The whole surface of the burn and the surrounding skin is rubbed vigorously. Blisters are rubbed off with all dead tissue. No blister is pricked, nor is the dead skin allowed to remain to keep fluid pent up only to be infected by the organisms of the skin. Dead tissue is more effectively and easily rubbed off than removed with scissors and forceps. After thorough cleansing a dressing of sterile gauze wrung out of the alcohol is applied. Over this dry gauze and wool are applied, and then a bandage. Under chloroform the same process is repeated daily. Every other day will not do, for the burns begin to be septic and offensive. The parts are rubbed, not wiped, with the gauze wrung out of alcohol. On beginning to remove the dressing it will be found stuck to the surface. By pulling upon it bits of dead tissue are satisfactorily removed. The dressings are continued for about eight days when burns which have not destroyed the whole thickness of the skin will be found in such a clean state that boroglyceride gauze or gutta percha tissue can be applied as a dressing without any pain. It is striking how rapidly the burns now heal under the boroglyceride. If they become infected again one cleansing with alcohol followed by one alcohol dressing will render them again aseptic. Burns which involve the whole thickness of the skin take longer on account of the sloughs. Under the alcohol treatment these become black, dry, and shrivelled up, and can be torn off or dissected off with a sharp scalpel and forceps. Valuable time will be lost if the surgeon waits for the sloughs to separate. The best results follow the cutting off of the sloughs, for they are not sodden and the surface is aseptic. A scalpel must be used, for it leaves a clean cut with no track of dead and injured cells as a scissors does. Dr. Milligan has employed this treatment during five months for a great number of burns in the Children's Hospital, Melbourne. One case of extensive and deep burns was fatal. Two large duodenal ulcers were found at the necropsy, but at the time of death (twelfth day) the burns were in an aseptic state with all the sloughs removed. In all the other cases healing was most satisfactory. They included burns and scalds of almost all parts of the body, some deep, some on the face, and some on the buttocks where cleanliness is difficult to maintain in young children. The daily use of chloroform did not prove in any way injurious. There was never any vomiting to interfere with the taking of food, so necessary for a burnt child. Anæsthesia must be employed, otherwise the application of alcohol would be too painful. When the children recover from the anæsthetic they feel no pain and are quite happy.

THE HISTORICAL MEDICAL EXHIBITION.

Among other historical medical objects of exceptional interest that have been secured for the Historical Medical Exhibition, organised by Mr. Henry S. Wellcome, and which will be opened in London during the meeting of the International Medical Congress in the coming summer, are many personal relics of Dr. Edward Jenner, the discoverer of vaccination. These include the original lancets and scarifiers he employed during his first experiments, his case and account books, his snuff-box, medicine chest, and many other interesting articles. A collection of Jenner's autograph letters has also been lent to the exhibition, together with the armchair from his study in which he died. Other objects connected with the life of Jenner are also to be exhibited, including many valuable portraits of himself and family, painted at different periods, the illuminated addresses presented to him, together with the freedoms of the cities of London and Dublin, also medals, and other documents of special interest. Concerning the history of anæsthesia many interesting relics are to be exhibited, beginning with the original autograph journal and manuscripts of Henry Hill Hickman, for whom it is claimed that he was the discoverer of the application of the principle of anæsthesia by inhalation for surgical operations. His experiments on animals were made in 1823. Personal relics of Sir James Simpson, and some of the earliest forms of apparatus for administering chloroform and ether will also be shown. Those who possess any objects connected with the history of medicine and the allied sciences, and who would be willing to lend them, are asked to communicate with the Secretary, 54A, Wigmore street, London, W., who will be pleased to forward a complete illustrated catalogue to anyone interested.

CULTIVATION OF THE VIRUS OF POLIOMYELITIS.

Dr. Simon Flexner's brilliant researches on poliomyelitis have recently been carried an important step further. He in association with Noguchi, by using methods devised by the latter for the cultivation of the *spirochæta pallida*, has now succeeded in procuring what appear to be true cultures of the virus of infantile paralysis; an account of these experiments will be found in the *Journal of the American Medical Association* for February. The organism has appeared to multiply in a mixture of ascitic fluid and filtrate from the infected nervous tissues as was shown by Flexner and Lewis, but the original fluid alone appeared to be capable of producing the disease and not any subcultures. In the new media employed minute colonies clouding the tube make their appearance after several days culture under anaerobic conditions, and these colonies seem to be made up of globular bodies, varying in their arrangement, averaging $0{\cdot}15\mu$ to $0{\cdot}3\mu$ in size and showing a reddish violet with Giemsa's stain. Similar bodies have been demonstrated by Noguchi in films from infected nervous tissues. The third generation from the human disease and the fifth in the case of monkeys have produced typical poliomyelitis. The observers are, however, cautious, and further experiments are being made with later generations in order to exclude the possibility that the results are due to the carrying over of the original virus from culture to culture. In this disease we have apparently a visible though filterable virus.

FATAL AIR EMBOLISM DUE TO ATTEMPTS TO INDUCE ABORTION.

WE recently referred to an accident which may occur in the attempt to induce abortion by injecting fluids into the uterus—the production of fatal air embolism.[1] So far as we know no case has been recorded in this country, and yet, as we remarked, four cases have been reported in one Australian medical journal[2] in a little over three years. In the *New Zealand Medical Journal* for November, 1912, is published a paper read before the Canterbury Division of the British Medical Association by Dr. J. W. Crawshaw which is further evidence that this is a common method of inducing abortion at the Antipodes. Two cases have been before the courts in the North Island of New Zealand, in one of which a conviction was obtained. Dr. Crawshaw reports the following case from the South Island. On May 17th, 1912, he was called to the house of a woman whom he found dead. She had four living children and had had five or six miscarriages, the last in August, 1911. Her health, except for anæmia, caused by severe hæmorrhages at several of these miscarriages, had generally been good. When Dr. Crawshaw arrived there was a woman in the house who was uncommunicative. All she would say was that while her back was turned she suddenly heard a cry and the sound of a fall and found the deceased on the floor perfectly still. On Dr. Crawshaw's arrival the body had been placed on the bed and was quite warm. There were no signs of violence. The pupils were of medium size. The clothing was unfastened on the chest and was wet. It had been unfastened after the woman fell and the wetting was due to an attempt to make her drink. The rest of the clothing was not disarranged; indeed, the chemise was tucked into the drawers very tightly. There was no hæmorrhage or discharge from the vagina, and the underclothing was dry and showed no stains. A necropsy was made 17 hours after death. The body was well nourished. Examination of the organs *in situ* showed that the uterus was of the size of a four months' pregnancy. The liver and spleen appeared to be slightly enlarged. In the thorax nothing abnormal was noticed. It was decided to make a detailed examination of the abdomen first. The liver was first removed. Numerous large bubbles of gas escaped from the divided portal vein. On detaching the liver from the vena cava inferior a great quantity of gas escaped from that vessel. The liver was slightly enlarged but on section quite normal. The uterus, vagina, tubes, and ovaries were removed *en masse*. On dividing the ovarian and uterine vessels gas escaped from the veins on both sides in a continuous succession of bubbles, and pressure on the uterus forced out a considerable quantity of air from the cut ends. The uterus was of a peculiar mottled appearance, purple areas alternating with others of a lighter greyish colour. The muscle felt soft and flabby, no rigor mortis being apparent. On rolling the uterine wall between the finger and thumb a crackling sensation was felt, resembling that of surgical emphysema. On section of the uterine wall this was found to be due to air in the venous sinuses, which issued from all parts of the cut surface on pressure. The external os was patulous, admitting the index finger easily. The uterus contained an unruptured ovum which was separated along the whole of its posterior and lateral surfaces and for a considerable part of its anterior surface. There remained attached only the upper two-thirds of the placenta with a small area of membrane at the fundus. In spite of this detachment no hæmorrhage had occurred. The cervix and vagina were carefully examined for injuries with negative result. The ovum contained a male fœtus of four months' development. The heart and lungs were removed together from the chest. On dividing the superior vena cava a large quantity of air escaped. The heart was of normal size. The right auricle and ventricle were empty except for a small quantity of frothy blood. The pulmonary arteries contained much frothy blood. The left side of the heart did not contain any air bubbles. The mitral valve was slightly thickened, and there was slight atheroma in the first inch of the aorta, but the coronary arteries were normal throughout their whole extent. The lungs and brain were normal. The conclusion come to was that death was due to the entrance of air under pressure into the uterine cavity separating the ovum and entering the uterine sinuses through the open vessels of the placental site. Hence it travelled by the ovarian and uterine veins to the inferior cava, heart, and pulmonary arteries. Probably the air was injected by inserting the nozzle of an enema syringe into the cervix. The fact that no blood was found in the uterine cavity was attributed to high pressure of the air. We may add that in the previous cases blood or bloody discharge was found at the os uteri and vulva.

THE DUTCH AMBULANCE AT THE BALKAN WAR.

Dr. van Ommeren, of the Dutch ambulance in Constantinople, has sent an interesting letter to the *Tijdschrift voor Geneeskunde*, in which he describes the deplorably filthy condition in which patients were brought in. Many who had been operated on were lying in a bath of pus. When, however, these had been cleansed and their dressings changed regularly, abscesses and sinuses being opened, it was wonderful how rapidly they began to recover. He found the Roentgen ray apparatus often very valuable in showing the seat of mischief.

AMONGST the 15 candidates who have been selected by the Council of the Royal Society to be recommended for election as Fellows, Dr. William Bulloch, bacteriologist to the London Hospital, Dr. T. R. Elliott, assistant physician to University College Hospital, Dr. J. S. Flett, of Edinburgh, and Professor Arthur Keith are members of the medical profession.

Professor F. Gowland Hopkins, F.R.S., has been appointed President of the Section of Physiology at the meeting of the British Association to be held in September next at Birmingham.

Sir Arthur Branfoot, K.C.I.E., has handed over the presidency of the Medical Board of the India Office to Sir Richard Havelock Charles, G.C.V.O.

ROYAL DENTAL HOSPITAL.—The annual general meeting of the governors will be held at the hospital, *Leicester-square, London, on Thursday, March 13th*, at 5.30 P.M., Dr. Dudley W. Buxton, a vice-president of the hospital, in the chair.

THE MEDICAL PROFESSION IN INDIA.

(FROM A SPECIAL CORRESPONDENT)

THE medical profession in India is a heterogeneous body, and it is clear to me that our friends at home do not recognise this It is composed of men of various grades of ability and education, of different class and caste, who, speaking generally, are all actuated by the same high motives and work together in loyalty to the Government and the people Speaking generally again, the official in India is the least self seeking of mortals, he is, as a rule, devoted to his duty, and although he will draw without a blush a hugely inflated T A (travelling allowance) he will repudiate with scorn the very suspicion of a bribe This official honesty is not confined to the European, it extends to all subordinate native officials, who are much touched in their honour by any reflection upon their official probity It is this high feeling which, combined with the semi military organisation of the Government, where every man has his rank and precedence, makes for that smooth and efficient working together of men of all classes, castes, and religions which distinguishes the Indian services and, not least among them, the medical service There is, of course, jealousy and discontent, which is increasing as the native is becoming more and more educated, but up to the present this has not been intruded into official relations, nor has it been allowed to mar the efficiency of the services How long such a state of things can go on it is impossible to say, but we may hope that reforms will be instituted before anything damaging to the services can occur

The Indian Medical Service

Classified according to duties performed, salary received, rank and precedence, all the things which in India really matter, the last not least, we may describe the Medical Service as composed of the following units —

1 The high officials

2 Officers of the Indian Medical Service in military employ A separate civil medical department for India is desired by many

The Appointments of District Surgeons, Chemical Examiners, and Sanitary Commissioners

3 Officers of the Indian Medical Service in charge of civil districts and jails those on sanitary duty as Commissioners and Assistant Commissioners, who have taken up analytical chemical work (chemical examiners), &c, comprising a class who receive salary and allowances as a rule adequate to their needs, and are able in some places occasionally to add to their income by undertaking private work

District surgeons are generally hard worked, they have a large district, and are responsible in a supervisory capacity for the dispensary medical work that is done by subordinates They have much administrative work of a trying character to perform, and are expected to make periodical visits of inspection to the medical institutions and dispensaries within their districts They lead a life very fully occupied by official duties and have little leisure for private practice, the opportunities for which vary in the different districts Any additional income they are able to make in this way must break into the little leisure they can allow themselves and in many places they are driven to undertake private cases from the want of other competent medical aid within a reasonable distance of the villages in the district The district surgeon must be distinguished from the civil surgeon of a town or station who is not infrequently quartered in or near the same town

Chemical examiners may be said to be side tracked They are recruited from specially chosen junior officers who receive an appropriate training and as vacancies occur succeed to senior positions They receive an adequate salary, and where there is a medical college, as in Presidency towns, they hold the professorship of chemistry and draw an additional allowance They are permitted to undertake private analytical work and in this way to add to their income fees which in some towns amount to more than in others Their work is congenial and not too exacting, and they have reason to be well satisfied

Sanitary Commissioners and their deputies have plenty of touring work Their chief duties are to give advice to municipalities on sanitary matters, advice which very often cannot be, or is not, carried out A scheme for the improvement and strengthening of the sanitary service in India has recently come into operation, under a Government of India resolution of May, 1912 The improvements are in the direction of decentralisation of control, of widening the field of recruitment by throwing open the higher posts to fully qualified Indians of proved aptitude, and of strengthening the staff in some of the provinces in which it is at present inadequate Local Government Boards are empowered to select their own Sanitary Commissioners from the officers serving in the *Provincial* (not I M S) sanitary departments under certain conditions, and the larger municipal cities are to have medical officers of health of the first class—i e, officers possessing registrable qualifications and a British Diploma in Public Health The prospects in the sanitary department are seen to be thus improving, and the pay is satisfactory

The Position of Civil Surgeon

4 The civil surgeon of a large town or station holds a coveted position He is in medical charge of the Government officials located in the town, who are entitled to his services during illness, as in some cases are also their wives and children The nature of the service varies according to the rank of the official The civil surgeon is usually assisted by a subordinate officer, and Government servants below a certain grade are entitled only to the services of this subordinate under the supervision, as it were, of the civil surgeon In places where there is no special health officer he is responsible for these duties in addition, but they are usually quite inconsiderable, for where they amount to anything of importance there is usually a special officer The civil surgeon is brought into contact with the unofficial population, both European and native, among whom he is able to carry on a lucrative private practice It is in connexion with the civil surgeon and the Presidency town hospital surgeon, that an agitation has arisen against what is called the monopoly by the Indian Medical Service of civil appointments and private medical practice, which culminated in a memorial to the Secretary of State for India by the independent medical profession of Bombay It would be incorrect to say that there are no grounds for such an agitation, but at the same time it is not my intention to suggest that all the grounds are good or that all the changes suggested in the memorial referred to are desirable in the public interest So far as I am personally aware these positions have been in a few instances abused Where an official is entitled to service it may have been given sometimes reluctantly unless a fee was forthcoming, and when a man or his wife or child is ill he is in no mood to accept unwilling or hurried medical aid, and he will pay and say nothing more about it Again, a man who is entitled to subordinate medical aid in ordinary circumstances will sometimes desire superior service and again he will pay and be silent The customary fee for an officer of the Indian Medical Service to demand and receive is 15 rupees (£1) for a consultation or visit, and the medical cost of a lengthy illness is therefore not inconsiderable It must also be understood that he acts in most cases as a general medical practitioner in attendance on the patient, and not merely in a consultative capacity to his subordinate In a "good" station the civil surgeon is a much occupied man, but *not* only with official duties

Professorial and Hospital Appointments

5 Officers of the Indian Medical Service at Presidency towns, employed as professors at the Medical College and as physicians or surgeons to the general and special hospitals are the real Indian consultants and specialists, though they do not limit themselves to consultative work nor even to their special branches of medicine and surgery These appointments are the plums of the service They fall to specially selected officers who, as a rule, very worthily fill them Their duties as medical offi[illegible] of the day, say, from [illegible] their serious cases in [illegible] is given in the morning during the hospital [illegible] addition they have lectures to deliver at the Medical College, generally in the afternoon Their time is thus seen to be fairly fully occupied, but not so much as to preclude private practice, which, indeed, they cannot avoid, both on account

of their position and reputation in the Presidency, and the constant and urgent calls to which they are subject.

The Provincial Medical Service.

6. The assistant surgeons (Provincial Medical Service). This service is recruited by competition among the medical graduates of the Indian universities. They act in various capacities as health officers of second-class municipal districts, as assistants to district surgeons, to civil surgeons, to professors at medical colleges, to physicians at hospitals, to the chemical examiner, &c., all which posts are also open to the warrant officers of the Indian Subordinate Medical Department. A few members of the Provincial Service hold English registrable qualifications, and are dissatisfied with the bar to their promotion to positions reserved for officers of the Indian Medical Service. They seem to have much justice in their claims for better consideration, and there is no doubt that they will obtain it, and that those who know the Indian Medical Service most intimately would rather that this were so than that any spirit of soreness were fostered.

The Indian Subordinate Medical Department.

7. This is a military department of warrant and non-commissioned officers, but not therefore a department whose officers are confined to military duties. As stated above, the warrant officers of this department share with members of the provincial service some of the most coveted posts in that service. It is recruited locally through *Governmental* competitive examinations of applicants for entry to the medical colleges. After four years' teaching these students are again examined *Governmentally* and drafted into the service. It will be seen that it is not necessary for them to have passed an examination of the medical faculty of a university to obtain their positions. Like the Indian Medical Service, of which this is the subordinate department, it has a military and a civil side. On the military side it is distinct and definite, but on the civil side it merges into the provincial medical service, so far at least as duties are concerned. Wherever he may be, an officer of the I.S.M.D. is under military discipline. This is not the case with an officer of the provincial service in theory, but in practice the difference amounts to very little, for the whole organisation of the Indian Government is semi-military, and discipline and subordination are strictly observed. The I.S.M.D. has, roughly, two divisions. The upper division is composed of men who are presumed to have some white admixture of blood. They possess European names, use the English language as their native tongue, are of the Christian religion, of English dress and habit, English outlook and mind. Some of them are the sons of English soldiers and are English in every respect, the great majority are of mixed English and Indian race, while in the case of a few it is doubtful if at any period in their ancestry occurred an infusion of European blood. They constitute a set of highly efficient and loyal men, who, subject to the limitations of their opportunity and education, are a creditable body of medical practitioners. In civil posts they have opportunity for private practice which they carry on with credit to themselves and satisfaction to their patients. They frequently rise to honorary commissioned rank. On retirement they practise in the larger towns and stations and are the usual medical attendants of the European and Eurasian population of these places, often whether or not their patients are entitled to the gratuitous services of the district surgeon or his subordinate. The lower division of this service is composed of natives, educated, examined, and passed in a similar manner. The standard of education is lower. They rank as non-commissioned officers, but rise to warrant rank corresponding to subadar or jemadar. They are attached in subordinate capacities to hospitals and do most of the outlying district work at dispensaries. When a district surgeon is said to have the medical charge of the population of a district, numbering "1¼ millions of people," it means that he has these subordinate officers scattered over the district at dispensaries which he visits at stated intervals.

The Independent Medical Profession.

8. In addition to the seven classes above described, who are all Government officials, there are also medical practitioners in India who are non-official. These are made up of European medical men, the health officers of the large cities, railway doctors, plantation doctors, doctors at mills and other commercial undertakings, and a large body of native practitioners, with and without European qualifications, who may be termed the independent medical profession of India.

Such, then, are the components of the medical profession in India, that is, of the profession which studies and practises Western medicine, severed by caste, race, and religion, but bound together by the tradition and ethics of the profession, and in spirit, if not in letter, by the Hippocratic oath. This bond of union has been, and will be, denied. One is constantly told that there is no practice of medical ethics in India. It may be that their standards do not conform to those of the British practitioner at home in all particulars. But the reality and the spirit are there, and show their presence in the face of different circumstances. The necessity of the patient is the controlling factor to the physician, and all interests are subordinated to it. This, at any rate, is the impression made upon me, who, understanding the language and manner of life of the Mohammedan and Brahmin or other Hindu, have been enabled to enter their homes and share their thoughts. Of the Hakeem and Vaythian, professors of native medicine, it is not necessary to say anything more than that they still drive a lucrative business.

Consideration of the Question of Reform.

From all that has been said it will be seen that in the main the medical service of India is efficient and satisfactory, but there are certain aspects of it where reform is both desirable and necessary. In considering what is to be the character and extent of reform, the question must be looked at from all points of view. In the first place it must not be forgotten that there is a Governmental aspect—namely, the civil interests of the population at large, and more especially the poorer part of it, and the military exigencies of the English occupation of India. It is stated that it is necessary to have a large reserve of officers who could be made immediately available in time of need, but who are not required for present military purposes, and who are thus economically provided for in civil posts.

If it be granted that this is a paramount consideration, an inquiry might still be necessary as to the numbers in reserve in civil posts, and it may fairly be imagined that the result of such an inquiry would disclose a large excess. In regard to the needs of "the teeming millions of India" it will make no difference whether the district surgeon be a civil or military officer, for they seldom see him unless, being seriously ill, they find their way to the district hospital. Their lesser needs are provided for in the persons of the sub-assistant surgeons at the dispensaries. A civilian surgeon will probably give them as good treatment when they come under his hands as the military man now in office, but he will not give them better. Therefore, from the Government's point of view, the change from a soldier to a civilian in the civil posts seems quite unnecessary.

From the point of view of the white population of India something may be said in favour of a separate civil medical service in India, composed of officers on a graded scale, not subject to sudden and irregular transfer from one station to another. This will apply more especially to the civil surgeon of a station who is the chief private practitioner, and with more force in the case of the non-official population, who are not, like the officials, subject to frequent and sudden transfer.

It is true that the Government are not called upon to provide medical aid for non-official Europeans, who are in most cases well able to pay for it themselves, but there being usually no other medical practitioner in the town of the same skill and standing as the civil surgeon, they are perforce obliged to avail themselves of his assistance. At present private practitioners of the requisite qualifications and standing are not available, but if the powerful competition of the service doctor be withdrawn this could be left to time and circumstance to supply.

We now come to deal with the interests of the officers of the Indian Medical Service and with those of the independent local profession, interests which are opposed to each other. In a moderate and fair-minded article on this subject which appeared in the *South of India Observer*, March 19th, 1910, it was stated that there is ample scope for the employment of indigenous talent in civil appointments not reserved of necessity for the accommodation of officers who are to be held available for army purposes. A large number of native medical men have been educated and thrown upon the country. Their efforts at private practice are frustrated by the existence of the subsidised private practitioner of the Government and they are at present ineligible for the civil posts which he holds Naturally they are dissatisfied It is true that the policy of Lord Morley has caused a few posts to be thrown open to them which were formerly closed but this policy will never be carried out in its fulness of intention until the liberty of private practice is withdrawn from the Indian Medical Service officer

It is stated that if this were done it would at once produce a detrimental effect upon candidature in England for the service The answer to such an argument seems to me to be obvious If the bait held out to candidates for the service is the very problematical one of a lucrative private practice after several years of service and a moderate amount of good luck it is the wrong bait to use Honourable conditions of service, good pay and prospects an ample period of privilege leave at reasonable intervals, are the considerations that should be used to attract men to exchange the security and comfort *of life at home for the numerous disabilities which every* career abroad must possess

There is another complaint against present arrangements which is not without foundation—the distribution of college professorships Under existing arrangements, the professorship of a subject goes with the holding of a particular civil appointment, and as transfers or promotions occur we are met with the spectacle of the professor of materia *medica of yesterday in the chair of surgery to day, or* the professor of jurisprudence or physiology of last week presently conducting the clinical teaching at the Government Maternity Hospital or Eye Infirmary Although the situation thus created is Gilbertian in the extreme it does not lead to such chaos as one might imagine and credit is due to the assistant professors locally qualified men, who are much more faithful to the subjects they profess because they are allowed to sit longer in their chairs Both in the interests of the students and of the public whom they will afterwards serve, it would be better if the principal and professors of the medical colleges were civilian medical men holding with their professorships the corresponding hospital appointments and free to undertake private practice in a consultative capacity At first it would be necessary to draw upon England to supply suitable men for these posts but there is no reason why in course of time in consequence of the better teaching they will receive natives should not become competent to hold them The Indian Medical Service cannot be expected to resign these posts without a strenuous struggle In Bombay the independent' profession has succeeded in gaining recognition at the Grant Medical College and in Madras the experiment is being tried of utilising the services of natives in honorary capacities as house physicians at the hospitals at Rayapuram and Royapettah

There remains only a word to say on the military aspect The regimental hospital system must give way to the station hospital organisation if officers in military employ are to be satisfied A scheme for such a change which showed only a negligible increase in cost was lately presented to the Indian Government but it was refused sanction upon that flimsy pretext alone Opposition of this character cannot be long sustained, and the future of the Indian Medical Service military branch seems hopeful It is tempting to suggest that the Indian Medical Service on its civil side should be swept away and replaced by a Civil Medical Service, but there are grave objections to such a proposal and so long as military exigencies exist it will never be carried The most *that can be hoped for is* a curtailment of the list of civil posts reserved for officers of the Indian Medical Service The absorption of the military branch of the service by the Royal Army Medical Corps is another proposal which might remove many anomalies but would doubtless create others no less real and complicated

If a fair proportion of civil posts were thrown open to the indigenous profession, if in regard to others of a higher status the present bar of entry were removed and if except by special permission individually granted, the privilege of private practice were withdrawn from Indian Medical Service officers *in exchange for more appropriate compensations* all parties might be more satisfied and none I consider would be unjustly treated but I can hardly suppose that the Indian Medical Service of whose admirable work and splendid traditions I have knowledge, will approve of the *suggestions*

ROYAL MEDICAL BENEVOLENT FUND.

His Majesty the King was graciously pleased last year to confer on the fund the title of Royal To celebrate this event it has been arranged to hold a dinner of those interested in the Fund and its Guild—both ladies and gentlemen

H R H Prince Arthur of Connaught has kindly consented to preside over the dinner, which will take place on Wednesday April 30th at the Hotel Cecil The following is the first list of stewards —

Adeline Duchess of Bedford
Aldrich Blake Miss L B
Allbutt Sir Clifford
Bailey Mr Cozens
Ballance Mr C A
Barling Mr Gilbert
Barlow Sir Thomas
Beale Dr Clifford
Berry Mr James
Bowen Dr W H
Bradford Sir J Rose
Bramwell Dr B
Broadbent Sir John and Lady
Browne Dr H Langley
Bruce Dr Ironside
Bruce Dr J Mitchell
Bruce Porter Dr H E B and Mrs
Brunton Sir Lauder
Buchanan Dr W
Burnet Sir Robert W
Bury Dr Judson
Buttar Dr C
Buzzard Dr F F
Byam Dr S H
Carr Dr J Walter
Edwards Mr F Swinford
Fagge Mr C H
Fairbank Mr J S A
Fenwick Mr E Hurry
Ferrier Sir David
Fowler Sir J Kingston
Fripp Sir Alfred and Lady
Fuller Mrs
Galloway Dr James
Gask Mr G E
Godlee Sir Rickman
Godson Dr Clement
Goodhart Sir James
Gordon Dr John
Gould Sir Alfred Pearce
Griffith Dr Walter
Hall Dr F de Havilland
Hardey Mr E F
Harris Dr and Mrs Wilfred
Hills Dr A Phillips
Hutchinson Mr Jonathan
Hutchison Dr R and Mrs
Katherine Duchess of Westminster
Kidd Dr Frank
Lockwood Mr C B
Luff Mrs
Lynch Dr J Roche
MacAlister Sir Donald.
McGavin Mr L H

Young Mr Parker

Communications relating to the dinner may be addressed to Mr G Bethell 11, Chandos street Cavendish square W, and subscriptions sent to the treasurer, Dr Samuel West 15 Wimpole street, W

At the February meeting of the committee 23 cases were considered and grants amounting to £222 voted to 20 of the applicants Appended is an abstract of the cases relieved —

Widow aged 63 of M R C S No income and supplements slight assistance from children by taking boarders Relieved twice £22. [illegible] aged 63 of M R C S Three children aged 13 to [illegible] by letting lodgings [illegible] aged 52 Met with [illegible] been incapacitated [illegible] to help Voted

£12.—Widow, aged 56, of L.R.C.P., L.R.C.S. Irel. Unprovided for at husband's recent death, and hopes to support herself by receiving boarders. Children only able to give very slight help. Voted £10.—Daughter, aged 51, of L.R.C.P. Irel. Has always been in feeble health, and is now incapacitated by a chronic complaint for which she has been promised admission to a hospital. Voted £5 now and £5 on leaving the hospital.—Daughter, aged 67, of late M.D. Edin. Used to have a small income, but was obliged to mortgage the property from which it was derived, and now receiving nothing owing to foreclosure by the mortgagee. Voted £12.—Daughter, aged 65, of late M.R.C.S. Was comfortably provided for by her father, but lost everything through the dishonesty of her trustee, and is now dependent on a small pension from another society. Relieved twice, £36. Voted £12.—Daughter, aged 62, of late M.R.C.S. Has had a school for several years, but now owing to competition finds it very difficult to meet her expenses and is obliged to maintain two mentally afflicted sisters. Relieved once, £10. Voted £12.—Deserted wife, aged 46. Since husband's disappearance a few years ago has supported herself in different ways, but is now in difficulties which she quite hopes will be temporary. Relieved once, £10. Voted £10.—Widow, aged 70, of M.R.C.S. Since husband's death 30 years ago has kept a lodging house, but now owing to failing sight and chronic rheumatism finds it very difficult to do the necessary work. Only income a few shillings a week from savings which have been invested. Relieved once, £12. Voted £5 and to be advised to apply for an Old Age Pension.—Daughters, aged 60 and 55, of late M.R.C.S. Entirely dependent on letting lodgings and both in feeble health. Relieved eight times, £96. Voted £12.—Daughter, aged 66, of late M.R C.S. Was fairly provided for at father's death but made most unfortunate investments which now yield only about 5*s.* a week. Relieved twice, £36. Voted £12.—Daughter, aged 44, of late F.R C.S. No income and health so indifferent that it is impossible to keep any post even when obtained Relieved 14 times, £117. Voted £12.—Widow, aged 63, of M.R.C.S. Quite unprovided for at husband's death several years ago and owing to a deformity has never been able to obtain regular work. Slight help from children. Relieved nine times, £106. Voted £12.—Daughter, aged 61, of late M.R.C.S. Has suffered for many years from a chronic complaint and been obliged to spend her capital both for treatment and maintenance. Relieved twice, £24. Voted £12.—Daughter, aged 56, of late M.R.C.S. Health too feeble for anything but light work and has to help support two sisters who are unfitted for any occupation. Relieved four times, £72. Voted £18.—Widow, aged 64, of M.D. Lond. After husband's death, about ten years ago, started a boarding-house at a seaside place, but lost all her capital, and is now unable to obtain suitable employment. Relieved twice, £24. Voted £12.—Widow, aged 57, of L.R.C.P. Edin. Slight help from children and lets lodgings. Relieved three times, £32. Voted £2, and case to be reconsidered.—Widow, aged 44, of M.B., C.M. Glasg. Quite unprovided for at husband's death a year ago, after a long illness, and obliged to endeavour to keep a home together because of her three youngest children, aged 10 to 4; slight help from elder children. Relieved once, £12. Voted £20.—Daughter, aged 35, of L.S.A. Has been offered a situation abroad, but requires a little help for unavoidable expenses. Relieved once, £10. Voted £5.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE quarterly meeting of this association was held at the Darenth Industrial Colony, Dartford, on Feb. 20th, under the presidency of Dr. J. G. SOUTAR.

Presidential Remarks: the Mental Deficiency Bill.

During the morning members inspected the various centres of activity in the colony, including the female and male workshops and wards for adult imbeciles, for the feeble-minded section, and for imbeciles under 16 years of age, three separate classifications of cases. At the luncheon which followed the PRESIDENT thanked, on behalf of the association, Mr. E. H. Helby, the chairman of the council committee, and Dr. A. Rotherham, medical superintendent, for the cordial welcome which had been extended and the interesting manifestations of good training which were so abundant in the institution. What was to be seen at Darenth was an eye-opener to many, even of those who knew something of such work. He thought that if Dr. Rotherham could only see his way to admit, for the remainder of their short recess, the members of the Cabinet and others in the House, to the institution, that House would rapidly pass, through all its stages, the Mental Deficiency Bill, for they would see that it would confer upon thousands of neglected persons the boons received by the inmates of Darenth Colony. He regarded it as one of the centres of education in the country, and much of that done here might well be copied by the public schools of the country, for here the limitations and potentialities of the pupil were ascertained, and the education directed accordingly. What tears, difficulties, and miseries would thus be saved!—Dr. ROTHERHAM briefly replied to the President's remarks, praising highly the capacity and efforts of the instructional staff, who were all skilled in their work before they took up the posts.—Mr. HELBY admitted that during the last nine years he had found great delight in doing what he could for the special class of case under care and training in this colony, and in the interests of the ratepayers of London. That it had been successful was due to the continuous and harmonious efforts of the medical and instruction staff. A few weeks ago he was a member of a deputation which attended before the Home Secretary. It was received by Mr. Ellis Griffiths, and he told that gentleman that if only a committee of the House of Commons would spend three hours at Darenth Colony it would do more good than three or four weeks' talking by people who, for the most part, had no real practical knowledge of the subject. He concluded by reading the following extract from the last report of the Commissioners in Lunacy, issued a few weeks ago: "We cannot conclude without expressing our pleasure and satisfaction with all we saw and learned during our visit of inspection, and we desire to record our impression that the work of the institution is being carried out on well-planned lines and with much skill and thoughtfulness in organisation, and that the object in view—namely, the adequate training and occupation of the imbecile class—is being attained in a most satisfactory and gratifying manner."

The meeting passed the following resolution on the subject of the detention of criminal lunatics in county and borough asylums:—

> That the Parliamentary Committee consider it is most undesirable that criminal lunatics be sent to county and borough asylums, and recommend to the council that the Association be asked to express this opinion to the Home Secretary.

A number of members were appointed to form a deputation on the subject.

The PRESIDENT alluded, in fitting terms, to the decease of Dr E. M. Courtenay (many years inspector of lunatics for Ireland), Mr. Joseph Bayley (48 years superintendent of St. Andrew's Hospital, Northampton), and Mr. S. G. Longworth (Distrct Asylum, Melton, Suffolk), and the meeting authorised messages of condolence to the respective relatives.

Treponema Pallidum in the Brain in General Paralysis.

A very important communication by Dr. GEORGE M. ROBERTSON, of Edinburgh, on a demonstration by Noguchi of the Treponema Pallidum in the Brain in cases of General Paralysis, was communicated to the meeting by Dr. WINIFRED MUIRHEAD. It showed that Noguchi found the spirochæte of syphilis in the brains of 12 out of 70 cases of general paralysis of the insane. The discovery was held to lay at rest much that had long been debateable. A section of the cortex, sent from Dr. Noguchi at Johns Hopkins Hospital, Baltimore, was on view under Dr. Muirhead's care. In all the cases the organisms seemed to have wandered into the nerve tissues; they were not found in the vessel sheaths.

Assistant Medical Officers in Asylums.

Dr. J. BEVERIDGE SPENCE read a paper entitled "Assistant Medical Officers in Asylums." He said that he had been for some time of the opinion that something should be done to improve the position of these officers; therefore he had been in full accord with the work of a committee of the Association on the matter, which had issued an interim report advocating a more advanced education for applicants for these posts. On the question of the facilities to continue study of psychological science at some centre—leave being granted for that purpose—the money factor had to be considered. It would perhaps be really necessary to increase the rate of remuneration in order to attract to the specialty the right kind of man, especially now that in other branches of the profession young men were advertised for at salaries of £400 and £500, with greater individual liberties than those known to assistant medical officers of asylums. In order to collect information on the subject, he had sent out forms to the superintendents of 94 asylums, and he gratefully acknowledged the courteous response of 92 of those gentlemen. Of these, 17 asylums had only one assistant medical officer. The average minimum salary of the senior assistant medical officer was £224, and the average maximum £309, exclusive of emoluments; the lowest being £150, rising to £200, and the highest £330, with a maximum of £430. The medical officers junior to the first seemed to vary from an [illegible] average maximum of £208; [illegible] £330, and the lowest £130, r [illegible] he found difficult of useful tabulation. In nearly every instance the medical superintendents approved of their senior assistant being a married man. Only eight regarded the idea unfavourably, while a few thought permission might be granted if accommodation were provided. There seemed, however, to be a feeling against this permission being granted to the second assistant. In 23 asylums there were now married assistant medical officers, while in 63 institutions these officers were not married. Dr. Spence then proceeded to consider the question of accommodation for married assistant medical officers, under three heads: (1) those who had rooms in the asylum main building; (2) those occupying a house on the asylum estate; (3) those who rented a house outside the asylum grounds; and made a comparison of the conditions and salaries of assistant medical officers of asylums with those of somewhat similar officers in prisons, to the advantage of the latter; and he counselled the continued efforts of the association to better the lot of the former, for it certainly was in sympathy with the aspirations of those gentlemen. He personally was in favour of an advance in the average salaries of assistant medical officers of asylums.

Darenth and its System of Industrial Training.

Mr. F. O. SPENSLEY, senior assistant medical officer, contributed a paper on this subject. He said that 40 years ago, at Hampstead Asylum, under the Metropolitan Asylums Board, an attempt was made to give the patients under 16 years of age [illegible] in schools. [illegible] he building [illegible] s. In 1874 the Board purchased a site for the separate treatment of imbecile children, meantime using the London Orphan Asylum at Clapton for the purpose, and Dr. Fletcher Beach was its first medical superintendent. In 1876 Darenth Training School was built. In the first year the patients' labour realised £66 5*s.* 7*d.* In order that the training might not be thrown away it was decided to build adjacent to the schools two blocks for 120 males and 120 females, adults, the Local Government Board insisting, however, on the elimination of the hopelessly "incurable," a term which the subcommittee altered to "unimprovable." Subsequently these two wards grew into the adult asylum, with 1052 beds. The author traced the growth of the institution to its present dimensions and many-sided activity, including mat-making, brush-making, wire drawing, pan work, envelope and paper bag making, tin-smith work, carpentry, book-binding, and printing. Drilling of the patients, of both sexes, was in full swing, to the obvious improvement of their physique and deportment. 835 out of the total of 1064 adult imbeciles were now undergoing industrial training. At present a wide and clearly marked line was drawn between the inhabitants of the pavilions and those of the remainder of the institution. They were admitted classified as feeble-minded, and were to be kept quite apart from the certified patients. It would, the author submitted, be difficult to find a better illustration of the impossibility of determining an arbitrary line of demarcation between an imbecile and a feeble-minded person. Among the so-called feeble-minded in the institution were many patients whose mental state was far below that of many of the certified imbeciles. He sketched a different classification, and described the methods pursued to encourage each patient to do his best, and therefore improve as far as possible. Mr. Bickmore was an admirable example of what a crafts-master of such an institution should be, and each tutorial member of the staff was an efficient instructor. Last year the industries realised £12,367, an increase of £8000 per annum in five years.—Dr. G. E. SHUTTLEWORTH, in discussing the paper, alluded to the transfer from Darenth to Rochester House, Ealing, of "*improvable*" cases in 1900 to 1904 for the purposes of industrial training. He agreed that there was very little difference between the high-grade imbecile and the ordinary feeble-minded person.—The discussion was continued by Dr. POWELL, Dr. R. L. LANGDON-DOWN, Dr. CORNER, and Dr. FLETCHER BEACH, and Mr. SPENSLEY replied.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Kent County Council.—Dr. W. J. Howarth's report of the year 1911 is among those which have a permanent value, apart from statistics, in the building up of the system of medical inspection and medical treatment. The year's record shows not only good work done but solid foundations laid for better. District nurses have been engaged to do, chiefly, "following-up" work. A whole-time nurse has been appointed to stimulate the adoption of a higher standard of cleanliness, and reinspection has been made definite and certain by the institution of a medical log-book of defective children with a continuous record of observations by inspectors and teachers. The attendance officers also assist by arranging for excluded children to attend medical inspections, and a nurse attendance officer has proved of considerable value. The actual work of inspection is carried out by a staff of whole-time and part-time officers arranged so as to allow of its transfer to whole-time medical officers of health as occasion presents. The part-time inspectors are paid a fee of 1*s.* per inspection, *plus* £1 for every 1000 acres in the area and £1 per annum for each school. Total payment per child must not exceed 3*s.* per child inspected or 4*s.* in the Isle of Sheppey. The inspectors arrange their own time for visiting the schools, but give a clear week's notice to the school medical officer of appointment suggested. The cost per inspection works out at 1*s.* 10*d.* for the salaried men and 1*s.* 5*d.* for the part-time men in urban districts, and 2*s.* 9*d.* per child in rural districts. The higher rate in rural districts is due to the fewer children who are examined. Interesting tables are given showing the divergencies between the opinions of inspectors with regard to the existence of defects needing attention. Records of inspections by 20 officers are given, and with regard to teeth the percentage (urban districts) stated to be requiring treatment varies from 27·1 in one case to 0·64 in another, and in regard to visual defects (rural districts) from 15·3 per cent. in one case to 2·9 per cent. in another. To ensure greater uniformity the school medical officer proposes to arrange a conference of inspectors for the discussion of these variations. While no attempt has been made by the Education Committee to provide for treatment by means of clinics or by arrangements with medical practitioners or hospitals, a fair proportion of children have been helped to treatment by following-up methods and the work of care committees. An outbreak of scabies, however, was successfully tackled by the nurse acting under the supervision of the part-time school doctor. Of the cases treated it is interesting to note that more than one-third were dealt with by local practitioners. The steps taken to further medical treatment have included the issue of a circular by the Education Committee inviting the coöperation of school managers, and a meeting of the school managers of the Sheerness schools and the school medical officer to discuss this circular, and a letter from Lord Harris offering substantial help. The possibility of treatment has also been forwarded by the defining of means available to give effect to proposals for treatment by the Education Committee.

Manchester City Council.—The report of the school medical officer (Dr. A. Brown Ritchie) for 1911 is included as a section in the general report of the Education Committee, and constitutes about one-third of a very imposing document crammed with information and suggestive material for future work. It seems a pity that the great mass of these reports cannot in some way be boiled down to facts and figures necessary for each locality's work, and the valuable ideas and suggestions for general application (which emerge from the work of every school medical officer) made the common property of all. From this Manchester report many excellent suggestions emerge, but need a large amount of digging out of the framework (laid down by the Board of Education) in which they are embedded. We make the suggestion with diffidence that the report should be in two sections: facts and figures for local work, and facts, figures, and suggestions helpful to other authorities. Manchester pays special attention to infectious diseases; measles, German measles, and whooping-cough have now been made compulsorily notifiable, and one assistant school medical officer is almost entirely employed in infectious diseases work. The other assistants are engaged every day of the week (except Wednesday, which is spent in office work) from 9.15 to noon and from 2 to 4 on routine inspection; 4 to 4.30 P.M. and any time not filled in by routine is devoted to special cases. It would surely be better for the efficiency of the work to vary this cast-iron schedule. During the year under review ringworm cases have been allowed to attend school if having the hair cut short, wearing washable caps, and undergoing medical treatment and submitting to periodical inspection by the school medical officer. The duration of the disease has been shortened, and no case of infection to another child in school was discovered. Over 600 children with ringworm attended school and made 4051 attendances at the observation clinic. Manchester is particularly active in providing for special classes of defective children; not only mentally defective, blind, deaf, and crippled children are dealt with, but also consumptive, epileptic, and stammering cases. In the education section of the report an account is given of the institutions concerned, illustrated from photographs. Six classes for stammerers were held during the year, attended by 58 boys and 5 girls. A "fair number" of successful cases are reported. Ten boys underwent a second course, and there is a waiting list of applicants for treatment. Manchester's activity in special departments is reflected in special reports from school doctors, one on "Backward Children" (Dr. H. Herd) is a very suggestive study. The children are divided into three groups, the first marked by serious physical weakness or disease (including sense defects); the second mentally backward *per se* (some of these latter were physically above the average); the third with physical and mental defects. Among other special reports is one by Dr. E. F. M. Neave on "The Effect of Environment on Physique." This is studied from the height and weight statistics of 500 girls and 500 boys in poor, medium, and good schools, and also from these statistics applied to schools in a central district inside a circle of one mile radius, to schools outside this but within a circle of two miles radius, and to a third district within a circle of four miles. The respective densities of population per acre are 81·23, 51·52, and 13·51. The physical differences in the children are very striking and well displayed on a map of the city and a bold chart of the different groups of children dealt with.

Warwickshire County Council.—Medical inspection in Warwickshire is controlled by Dr. A. Bostock Hill, school medical officer, and largely carried out in the three divisions into which the county is divided by three school doctors who are also assistant medical officers of health. Over 1500 visits were made to the schools. Nine school nurses are also employed, and they are also health visitors and so deal not only with the school child found defective, but with the whole household, "from the point of view of the prevention of disease, as well as its palliation." Further increase in the nursing staff is contemplated. A good deal of treatment has been secured by the coöperation of hospitals. The school medical officer lays great stress on the maintenance of the self-reliance and independence of the parents. It is noted that some schools have no water-supply either for washing or drinking. An interesting point is the occurrence of 118 cases of goitre, 107 of which were discovered at routine inspection. Unfortunately the chief statistics for the county (number of schools, children on register, &c.) are not given in a handy form, and consequently comparison of statistics is difficult. A useful hint which might be widely taken up is that for the institution of "ventilation drill."

Northamptonshire County Council.—During 1911 a considerable step forward in Northamptonshire was made by the holding of a conference of representatives of the managers of public elementary schools and members of the education committee, and the consideration there of medical treatment from various points of view. Children with defective vision are now offered treatment by the assistant school medical officer (Dr. J. H. Mason), under the supervision of Dr. H. L P. Hulbert (school medical officer), and spectacles are supplied, on contract, at from 2*s.* to 2*s.* 6*d.* a pair. Of all cases needing treatment (including visual defects), 71·4 per cent. in urban districts and 65·1 per cent. in rural districts obtained this treatment, but the treatment of cases needing operation for removal of tonsils and adenoids was not satisfactory.

Bedfordshire County Council.—No arrangements for treatment otherwise than persuasion by the school medical officer (Mr. W. J. Butcher) is adopted in Bedfordshire, and cases appeared to be "followed up" only by inquiry from the children by the head teacher. Figures so obtained are, of course, not to be relied upon. But a nurse school attendance officer and health visitor has been appointed to deal with following up and with verminous children. Sanitary conditions in some schools are very primitive and in others no facilities for washing exist. Medical inspection appears to be at an early stage of its development in Bedfordshire.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,764 persons, 8894 births and 6178 deaths were registered during the week ended Saturday, March 1st. The annual rate of mortality in these towns, which had been 17·2, 17·2, and 17·3 per 1000 in the three preceding weeks, further rose to 18·0 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 16·8, against 17·4 per 1000 in London during the same period. The death-rates last week in the several towns ranged from 8·6 in Wallasey, 9·6 in Ilford, 10·0 in Ealing, 10·1 in Acton and in Great Yarmouth, and 10·5 in Smethwick, to 27·6 in West Hartlepool, 30·9 in Stockton-on-Tees, 32·0 in Swindon, 32·5 in St. Helens, and 33·2 in West Bromwich.

The 6178 deaths from all causes in the 96 towns were 247 in excess of the number in the previous week, and included 506 which were referred to the principal epidemic diseases, against 458 and 482 in the two preceding weeks. Of these 506 deaths, 263 resulted from measles, 78 from whooping-cough, 76 from infantile diarrhœal diseases, 52 from diphtheria, 29 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5 per 1000, against 1·3 and 1·4 in the two preceding weeks. The deaths attributed to measles, which had been 200, 217, and 243 in the three preceding weeks, further rose to 263 last week, and caused the highest annual death-rates of 1·7 in Birmingham, 2·0 in Sheffield, 2·2 in Bath and in Bootle, 2·9 in Eastbourne, 4·6 in Plymouth and in Wigan, 9·1 in West Bromwich, and 10·5 in St. Helens. The deaths referred to whooping-cough, which had been 78, 70, and 78 in the three preceding weeks, were again 78 last week, and included 28 in London, 4 in Liverpool, and 3 each in Bristol, Stoke-on-Trent, Salford, Rotherham, and Newcastle-on-Tyne. The fatal cases of diarrhœa and enteritis (among children under 2 years of age), which had increased from 65 to 81 in the four preceding weeks, declined to 76 last week; 23 deaths were registered in London, 8 in Liverpool, 7 in Birmingham, 4 in West Bromwich, and 3 in Leicester. The deaths attributed to diphtheria, which had been 45, 53, and 51 in the three preceding weeks, were 52 last week, and included 8 in London and 3 each in Stoke-on-Trent, Liverpool, Barrow-in-Furness, and Rhondda. The deaths referred to scarlet fever, which had declined from 29 to 19 in the three preceding weeks, rose to 29 last week; 7 deaths were recorded in Birmingham, 4 in London, and 2 each in Bradford, Sheffield, and Aberdare. The fatal cases of enteric fever, which had been 18, 16, and 10 in the three preceding weeks, further fell to 8 last week, of which number 2 were registered in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily declined from 2112 to 1667 in the nine preceding weeks, had further fallen to 1659 on Saturday last; 183 new cases were admitted during the week, against 209, 196, and 180 in the three preceding weeks. These hospitals also contained on Saturday last 919 cases of diphtheria, 881 of measles, 316 of whooping-cough, and 44 of enteric fever, but not one of small-pox. The 1635 deaths from all causes in London were 59 in excess of the number registered in the previous week, and were equal to an annual death-rate of 18·8 per 1000. The deaths referred to diseases of the respiratory organs, which had been 373, 443, and 387 in the three preceding weeks, rose to 453 last week, and were 158 in excess of the number in the corresponding week of last year.

Of the 6178 deaths from all causes in the 96 towns last week, 196 resulted from various forms of violence and 499 were the subject of coroners' inquests. The causes of 46, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Nottingham, and in 71 other smaller towns. The 46 uncertified causes of death last week included 14 in Birmingham, 10 in Liverpool, and 2 each in London, Stoke-on-Trent, Warrington, Sunderland, South Shields, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,260,200 persons at the middle of this year, 1124 births and 895 deaths were registered during the week ended Saturday, March 1st. The annual rate of mortality in these towns, which had been 20·8, 20·4, and 18·7 per 1000 in the three preceding weeks, rose to 20·7 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 19·4, against 16·8 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rates last week ranged from 15·0 in Kilmarnock, 15·6 in Leith, and 16·3 in Perth, to 22·9 in Ayr, 23·9 in Dundee, and 24·1 in Aberdeen.

The 895 deaths from all causes were 87 in excess of the number in the previous week, and included 80 which were referred to the principal epidemic diseases, against 65 and 77 in the two preceding weeks. Of these 80 deaths, 55 resulted from whooping-cough, 7 from measles, 7 from infantile diarrhœal diseases, 5 from diphtheria, 4 from scarlet fever, and 2 from enteric fever, but not one from small-pox. These 80 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000, against 1·5 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 52, 39, and 50 in the three preceding weeks, rose to 55 last week, and included 41 in Glasgow, 5 in Edinburgh, 2 in Leith, 2 in Motherwell, and 2 in Clydebank. The deaths referred to measles, which had been 5, 3, and 7 in the three preceding weeks, were again 7 last week, of which number 4 were registered in Glasgow. The fatal cases of diarrhœa and enteritis (among infants under two years of age), which had been 10, 14, and 9 in the three preceding weeks, further declined to 7 last week; 3 deaths were recorded in Glasgow and 2 in Dundee. The deaths attributed to diphtheria, which had been 12, 8, and 7 in the three preceding weeks, further fell to 5 last week, and comprised 2 in Glasgow, 2 in Aberdeen, and 1 in Dundee. The 4 deaths from scarlet fever, 2 of which occurred in Glasgow, were slightly in excess of the average in recent weeks; the 2 fatal cases of enteric fever were registered in Glasgow.

The deaths referred to diseases of the respiratory system in the 16 Scotch towns, which had declined from 221 to 162 in the four preceding weeks, rose to 180 last week; 44 deaths were attributed to different forms of violence, against numbers declining from 34 to 23 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of this year, 693 births and 532 deaths were registered during the week ended Saturday, March 1st. The annual rate of mortality in these towns, which had increased from 20·4 to 24·1 in the four preceding weeks, declined to 23·1 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these Irish towns averaged 21·8 per 1000; in the 96 large English towns the corresponding death-rate did not exceed 16·8, while in the 16 Scotch towns it was equal to 19·4 per 1000. The annual death-rate recorded in the several Irish towns last week was equal to 26·9 in Dublin (against 18·8 in London and 21·7 in Glasgow), 23·4 in Belfast, 28·6 in Cork, 10·2 in Londonderry, 16·2 in Limerick, and 13·3 in Waterford, while in the remaining 21 smaller towns the mean rate did not exceed 14·5 per 1000.

The 532 deaths from all causes in the 27 Irish towns were 22 fewer than the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against 35 and 37 in the two preceding weeks. Of these 41 deaths, 16 resulted from measles, 11 from whooping-cough, 9 from infantile diarrhœal diseases, 2 from diphtheria, 2 from enteric fever, and 1 from typhus, but not one from small-pox or from scarlet fever. These 41 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; in the 96 large English towns the corresponding rate was 1·5, and in the 16 Scotch towns 1·8 per 1000. The deaths attributed to measles, which had been 18, 10, and 11 in the three preceding weeks, rose to 16 last week, and included 8 in Newry and 5 in Belfast. The deaths referred to whooping-cough, which had steadily increased from 1 to 8 in the four preceding weeks, further rose to 11 last week; 6 deaths were registered in Dublin and 2 in Waterford. The 9 fatal cases of infantile diarrhœa and enteritis, 6 of which occurred in Dublin, were equal to the average in the three preceding weeks. Of the 2 deaths referred to diphtheria, 1 was recorded in Dublin and 1 in Belfast; the fatal cases of enteric fever and of typhus occurred in Dublin.

The deaths referred to diseases of the respiratory organs, which had been 104, 115, and 142 in the three preceding weeks, were 143 in the week under notice. Of the 532 deaths from all causes, 164, or 31 per cent., occurred in public institutions, and 6 resulted from different forms of violence. The causes of 15, or 2·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: H. C. Whiteside to the *Suffolk*, temporary; and W. N. L. Cherry to the *Victory*, additional, for disposal. Surgeon: F. G. Hitch to Portland Hospital.

ROYAL ARMY MEDICAL CORPS SCHOOL OF INSTRUCTION.

Major Charles E. P. Fowler, R.A.M.C., to be an Instructor, vice Lieutenant-Colonel A. R. Aldridge, C.S.I. (dated Feb. 17th, 1913).

ROYAL ARMY MEDICAL CORPS.

Major Thomas C. MacKenzie, D.S.O., from the seconded list, is restored to the establishment (dated March 1st, 1913).

Captain James H. R. Winder to be Major (dated Feb. 27th, 1913).

Lieutenant Wilfred W. Treves is seconded for service under the Foreign Office (dated Jan. 7th, 1913).

Colonel F. J. Jencken, Assistant Director of Medical Services to the Colchester District, has been selected for appointment as Director of the Eastern Command, Royal Army Medical Corps, Staff Tour, to be held in the vicinity of Aylesbury. Colonel H. J. Barratt, Assistant Director of Medical Services to the Allahabad and Fyzabad Brigades of the Eighth (Lucknow) Division, has been selected for appointment as Assistant Director of Medical Services to the Bareilly, Garhwal, and Dera Dun Brigades of the Seventh (Meerut) Division of the Northern Army in India.

Lieutenant-Colonel R. J. W. Mawhinny, on arrival in India for a tour of duty, has been selected for appointment to hold charge of the Military Hospital at Jullundur. Lieutenant-Colonel R. J. Copeland has been transferred from Newcastle-on-Tyne to the Military Hospital at York. Lieutenant-Colonel J. W. Bullen has taken up duty at Meerut Cantonment on transfer from the Military Hospital at Agra. Lieutenant-Colonel J. S. Green, on completion of a tour of service in charge of the Military Hospital at Bangalore Cantonment, has been selected for appointment to hold charge of the Military Hospital at Fermoy. Lieutenant-Colonel H. M. Thompson, commanding the Military Hospital at Lucknow Cantonment, has been granted leave of absence home from India. Lieutenant-Colonel A. R. Aldridge has been appointed to the Eastern Command for duty at the Royal Herbert Hospital, Woolwich.

Major N. Faichnie has been transferred from the Military Hospital at Mhow to Delhi Cantonment and appointed to command the Military Hospital. Major D. J. Collins, lately specialist sanitary officer to the Dublin District, has taken up duty at the Military Hospital, Bangalore. Major J. G. Gill has been appointed to the Military Hospital at Rangoon on transfer from Maymyo Cantonment. Major S. G. Butler has been selected for appointment as Specialist in Operative Surgery at the Military Hospital, Curragh Camp. Major W. Power, on return home from Jamaica, tour expired, has been appointed to the Eastern Command for general duty. Major J. L. Jones has been selected for appointment to hold charge of the Military Hospital at Calicut, Madras Presidency. Major E. McDonnell, in charge of the Military Hospital at St. George's, Bermuda, has returned home, tour expired, and has taken up duty in the Eastern Command. Major T. B. Unwin has been transferred from the Military Hospital at the Guards' Depôt, Caterham, to London. Major F. W. Begbie has been transferred from Kamptee to the Military Hospital at Mhow Cantonment, and appointed Specialist in Operative Surgery to the Fifth (Mhow) Division of the Southern Army in India. Major J. Hennessy has left the Military Hospital at Cosham and embarked for a tour of service in India. Major E. B. Steel has been appointed to the Medical Charge of the Garrison at Exeter and Recruiting Medical Officer, in succession to Lieutenant-Colonel H. P. Elkington, transferred to Shorncliffe. Major J. S. Bostock has been transferred from the Military Hospital at Ranikhet to Agra Cantonment. Major J. H. Robinson has taken up duty in the First (Peshawar) Division at Headquarters on transfer from the Presidency Brigade, Calcutta. Major F. W. Cotton has left Fleetwood and embarked for a tour of service in India. Major A. M. MacLaughlin, lately specialist sanitary officer to the Scottish Command, has been appointed to hold charge of the Military Hospital at Madras Cantonment. Major R. J. Blackham, Honorary Surgeon to H.E. the Viceroy and Governor-General of the East Indies, has been placed under orders for transfer from the First (Peshawar) Division to the Third (Lahore) Division, and will take up the duties of Officer Commanding the Station Hospital, Jutogh, Simla Hills, on completion of special duty on H.E. the Viceroy's personal staff.

Captain W. H. S. Burney has been transferred from Donard to the Military Hospital at Attock Cantonment. Captain A. S. Williams, in charge of the Military and Cantonment General Hospital at Khanspur, has been appointed to the Dublin District. Captain J. W. S. Seccombe has been transferred from Taunton to the Military Hospital at Devonport. Captain F. W. M. Cunningham has taken up duty at the Military Hospital at Sialkot, on transfer from Kuldana, Murree Hills District. Captain R. E. W. Newman has been appointed for duty on the transport s s. *Dongola*, which left Karachi for Southampton on Feb. 26th with time-expired troops. Captain G. P. A. Bracken, in charge of the Military Hospital at Malapuram, Madras Presidency, has arrived home on six months' leave of absence from India. Captain F. W. W. Dawson has joined for duty at Ambala. Captain A. E F. Hastings has been transferred from the Military Hospital at Chatham to Sheerness. Captain T. W. O. Sexton has arrived home from the South African Command at the expiration of his tour of service. Captain R. H. Nolan has been appointed to the Scottish Command for duty. Captain G. F. Rudkin, staff surgeon, Fort St. George, Madras, has been granted six months' leave of absence home from India. Captain W. H. O'Riordan has been transferred from Ghangla Sali to the Military Hospital at Rawal Pindi Cantonment. Captain T. J. Mitchell has taken up duty at the Military Hospital, Lahore, on transfer from Dalhousie Cantonment. Captain T. T. H. Robinson has arrived home from India for duty at the expiration of his tour of service. Captain W. H. Forsyth has been appointed to the Southern Command for general duty. Captain A. E. S. Irvine has been transferred to the Home Establishment from the South African Command. Captain J. Fairbairn has embarked for a tour of service in the Sierra Leone Protectorate, West Africa.

INDIAN MEDICAL SERVICE.

The Honourable the Lieutenant-Governor of the United Provinces of Agra and Oudh has appointed Colonel C. C. Manifold, inspector-general of civil hospitals, to be a member of the Legislative Council of the United Provinces.

Lieutenant-Colonel D. T. Lane has taken up duty at Ambala Cantonment as Civil Surgeon, on return from leave of absence home from India. Lieutenant-Colonel R. C. Macwatt, second-class agency surgeon, on return from leave has been appointed to officiate as an Agency Surgeon of the First Class and as Civil Surgeon for Ajmer and Administrative Medical Officer in Rajputana State. Lieutenant-Colonel W. J. Buchanan, inspector-general of prisons in Bengal, has been appointed Companion of the Order of the Indian Empire.

Major V. G. Drake-Brockman has been selected for appointment as Civil Surgeon at Dera Ismail Khan. Major J. M. MacLeod has been appointed by the Foreign Department of the Government of India to officiate as Chief Medical Officer in Baluchistan, in addition to his duties as Civil Surgeon at Quetta during the absence on privilege leave of Lieutenant-Colonel A. L. Duke (Bengal). Major P. P. Atal has taken up duty as Substantive Medical Officer to the 129th Duke of Connaught's Own Baluchis. Major W. D. A. Keys, civil surgeon at Karwar, has been granted furlough and combined leave of absence home from India for one year.

Captain W. Tarr, civil surgeon at Pachmarhi, has been placed under orders for duty in the Nimar District. Captain J. S. O'Neill has been transferred from plague-prevention duty in the United Provinces of Agra and Oudh to ordinary civil employment in the same provinces. Captain A. G. McKendrick has been selected for appointment as Secretary to the Director-General of the Indian Medical Service in the Sanitary Branch, temporarily, in succession to Major S. P. James, placed on special duty. Captain F. W. Sumner, on return to duty from leave of absence, has been appointed to Farrukhabad. Captain J. A. S. Phillips has been selected by H.E. the Commander-in-Chief in India for appointment as Substantive Medical Officer to the 121st Pioneers, stationed at Quetta Cantonment, in succession to Captain I. D. Jones. Captain L. Hirch has arrived home on leave of absence from India. Captain D. Heron has taken up duty as Officiating Agency Surgeon of the Second Class under the Foreign Department of the Government of India at Seistan Consulate and has been appointed *ex-officio* His Britannic Majesty's Vice-Consul for Seistan. Captain N. S. Simpson has been selected for appointment as Medical Officer in Charge of Plague Prevention in the United Provinces of Agra and Oudh. Captain N. G. C. McVean has been granted six months' extension of his leave of absence home from India by the Secretary of State. Captain J. Anderson has taken over Medical Charge at Hazara on appointment as Civil Surgeon. Captain J. Smalley has been permitted to return to India by the Secretary of State. Captain H. C. Keates has taken up duty at Campbellpore as Civil Surgeon. Captain A. W. Howlett, on completion of special duty, has been appointed to officiate as Civil Surgeon at Mussoorie, in succession to Major C. Milne.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Cadet John Alexander Pridham, from the London University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Feb. 6th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Eastern Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major Edward J. Cross to be Lieutenant-Colonel (dated Dec 7th, 1912).

1st Lowland Field Ambulance, Royal Army Medical Corps: William Cooper Gunn to be Lieutenant (dated Jan. 31st, 1913).

1st Northumbrian Field Ambulance, Royal Army Medical Corps: Lieutenant Edward Baines Kitching, from the List of Officers attached to Units other than Medical Units, to be Lieutenant (dated March 5th, 1913).

Attached to Units other than Medical Units.—The undermentioned officers resign their commissions (dated March 5th, 1913):—Lieutenant-Colonel Robert B. Graham, who is granted permission to retain his rank and to wear the prescribed uniform, and Captain John A. Angus.

For attachment to Units other than Medical Units.—Thomas Albert Fisher to be Lieutenant (dated Jan. 20th, 1913).

DEATHS IN THE SERVICES.

On March 1st at his residence, 5, Cresswell-gardens, South Kensington, S.W., Surgeon-General Sir Colvin Colvin-Smith, K.C.B., honorary surgeon to the King, in his 84th year. He first served in the Burmese war, 1852–53, and was present at the operations before Rangoon in April, 1852, at the capture of the White House Stockade, at the attack and capture of Shor-da-goung Pagoda, and at the occupation of Prome (medal with clasp). During the Indian Mutiny he was with the Kamptee Moveable Column and the Saugor Field Division, taking part in the affairs at Khoonee Pass, Narampore, Neemkaira, Budgam, and minor affairs on the great Deccan road. He also took part in the operations in the Palamow districts and the march to Jubbulpore (medal with clasp). In 1882 he served as principal medical officer of the Indian contingent during the Egyptian War, and was present at the battle of Tel-el-Kebir and the occupation of Zagazig (mentioned in despatches, medal with clasp, bronze star, the third class of the Osmanieh, and was made a C.B.). He retired in 1884.

Deputy Inspector-General of Hospitals and Fleets Edward Higgon Evans, R.N., aged 83. He entered the Navy in 1853, became staff-surgeon in 1862, fleet-surgeon in 1876, deputy inspector-general in 1884, and retired in 1888. He served through the Crimean War with the naval brigade under Captain Peel, on the *Diamond*, and attended the wounded after the battle of Alma. He was lent to the *Vengeance* during the epidemic of cholera in 1854. He was present at the fall of Sevastopol, and in 1861 was surgeon to the mission to the Court of Monaco.

FIRST LONDON DIVISION, R.A.M.C.(T.F.).

Major-General W. Fry, C.V.O., C.B., in declaring open the headquarters of the Royal Army Medical Corps (Territorials) at Chelsea, on March 1st, said that, as commander of the First London Division, he hoped that that new establishment would not only be a centre for training and instruction, but also a desirable social meeting place for medical units. He had always found, he said, the medical units well up in numbers, and in many cases they were the only units in a corps which were up to full strength. One reason for this, he thought, was the closer bond of discipline that existed between the officers and men.

THE ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM IN ENGLAND.

Lieutenant-Colonel Thomas Horrocks Openshaw, C.M.G., R.A.M.C. (T.F.), and Colonel Clement Godson (T.F.) have been appointed Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England.

ARCHIV FÜR SCHIFFS- UND TROPEN-HYGIENE.

In the *Archiv für Schiffs- und Tropen-Hygiene* for January appears a paper by Dr. S von Prowazek on Tona, a disease of horses in Samoa, a granulation tumour which forms usually about the fetlocks. It is a hyperkeratosis, often a warty formation, commencing with increased proliferation in the stratum lucidum; numerous bacteria appear in sections, and spirochætæ also. It cannot yet be decided whether these swellings are due to local irritation or to constitutional infection. The best treatment is removal by knife or cautery at the earliest appearance of the disease, with subsequent application of white precipitate ointment. Dr. H. Werner, who has been promoted in the service of the Tropical Medicine School at Hamburg, reports a case in which an attack of blackwater fever was brought on by a glycerine enema, and intensified by another two days later. Dr. Braunert reports on a voyage he made through the Marshall Islands. Syphilis is widespread, affecting some 10 per cent. of the population; the women had only families of one or two children, which he ascribes to the frequency of gonorrhœa, and the late age (25) at which they marry, after years of irresponsible gaiety. The *infantile mortality is over 200. Dr. Schumacher reports* favourably on nastin in leprosy and Dr. Canaan reports on an epidemic of dengue at Jerusalem. The characteristic features were the early exhaustion, the dirty white-coated tongue, an [illegible] tive increase of mononuclears. [illegible] osely resembles pappataci fever [illegible] duration, 6 to 8 days against 3 to 5 days; the eruption occurred in nearly every case (head, arms, and hands, on the fourth day); in the other fever rarely oftener than in one case in three. The question of their identity or difference is left for the present unsettled.

Sir Arthur M. Branfoot, K.C.I.E., has handed over the presidency of the Medical Board of the India Office to Sir Richard Havelock Charles, G.C.V.O.

Correspondence.

"Audi alteram partem."

THE PANAMA CANAL AND MARITIME SANITATION.

To the Editor of THE LANCET.

SIR,—The letter of Dr. J. J. O'Connell, health officer of the Port of New York, directs attention to matters of great public importance.

Port sanitary authorities throughout the world are indebted to the United States Marine Hospital Service for the bulletin issued by them for a number of years and now issued by the United States Public Health Service. Valuable information is furnished by this document, whilst the weekly circular issued by the Local Government Board to authorities of British ports is a most valuable supplement. No one can question that any possible amplification of these systems which would tend to keep port medical officers of health all over the world more fully in touch with the sanitary conditions of the various ports, as well as with the condition of ships bound for their harbours, should be encouraged as far as it possibly can.

The opening of the Panama Canal will, from the point of view of sanitation, obviously have a great effect upon the ports of North and South America, but it will also, though to a less extent, have an effect upon British ports, analogous to that consequent upon the opening of the Suez Canal. The greater speed of vessels, the far more frequent intercourse, and the ease with which a voyage may be completed within the incubation period of, say, typhoid fever or small-pox, or within which plague infection may be kept alive by rats, are grounds for the closest attention to the sanitary condition of ports. Rigorous adhesion to the regulations laid down by the International Sanitary Convention of Paris (to which the United States is a party) should obviate the injury to sanitation and commerce which isolated action, prompted by want of knowledge or by fear, would occasion.

There is nothing in the sanitary condition of British ports to justify uneasiness, and the constant watchfulness in regard to incoming vessels ensures that imported disease will be effectually dealt with.

I am, Sir, yours faithfully,
E. W. HOPE,
Medical Officer of Health for the City and Port of Liverpool.
Liverpool, March 3rd, 1913.

To the Editor of THE LANCET.

SIR,—The letter you publish from Dr. J. J O'Connell under this heading is very interesting, and coming from so eminent an official as the health officer of the Port of New York may be regarded as a very important pronouncement of policy. The United States is so much ahead of any other nation in maritime sanitation that we may be quite certain that some very far-reaching scheme will be adopted for vessels passing through the Panama Canal. The exact lines of policy are not clearly indicated in the letter, and I am inclined to think that Dr. O'Connell is for the present rather feeling his way. It is, however, quite evident that this canal will be taken in hand in a very different manner to what has ever been the case with the Suez Canal. It is pleasing to note that whatever the details of the scheme are to be there is to be no undue interference with the natural flow of commerce, and that it is thought the 12 hours during which vessels are on the move can be utilised for inspection, and disinfection and fumigation where necessary.

I have some considerable experience of the conditions of a locked waterway, and whilst acknowledging that inspection can be very satisfactorily carried out on a moving vessel, I am somewhat sceptical as regards satisfactory disinfection and fumigation under a like condition. The Manchester Ship Canal is sufficiently wide to allow large vessels to pass one another with comfort and safety, but as these cannot get steerage way at the speed they travel two or three tugs have to be utilised for progression and balance. If similar conditions obtain in locking and navigating the narrow parts of the Panama Canal the fumigation boat will probably be regarded as a hindrance to navigation; at any rate, it would perform its function under extreme difficulties. Further, although there would probably be no tugs required on the lake, where the vessels will go at a much higher speed, one can again imagine how difficult it would be for a tender to keep in such correct relationship as to be able to pump, say, Clayton gas into her various holds. Steam disinfection of bedding, clothes, &c., could be carried out very well on such a tender, the articles being handed in at one end of the canal, and returned free from infection at the other.

Dr. O'Connell does not anticipate trouble from cholera, and, so far as this country is concerned, we do not anticipate trouble from yellow fever. We are mainly concerned with plague and (in my opinion) with small-pox. There would be no administrative difficulty in dealing with small-pox infection, as the methods adopted simply have concern with individuals and living quarters, but it would be very interesting to know the extent to which measures will be taken against plague infection. Will it be the policy to destroy all rats in "suspected" and "infected" ships by utilising some of the modern mechanical methods of forcing poisonous gases into the holds when full of cargo, and will the owners of merchandise be indemnified against possible damage? Whether vessels will be dealt with on the move or not there is, however, no doubt that infection can be thoroughly dealt with, if necessary, at either end of the canal before entry, and, to my view, without causing any great amount of delay. It will certainly be interesting to have more particulars, and I hope your correspondent will supply these in due course.

It is very gratifying to note that Dr. O'Connell regards the question from an international point of view, and there is no doubt that if his suggestion of transmitting information regarding infectivity of vessels to the ports to which they are bound be adopted, a most valuable asset will be placed in the hands of the port medical officers of this country. I am, Sir, yours faithfully,

W. F. DEARDEN,
Medical Officer of Health, Port of Manchester.
Manchester, March 3rd, 1913.

To the Editor of THE LANCET.

SIR,—Dr. J. J. O'Connell's letter in your issue of March 1st is not only of great interest but of vital importance, drawing attention, as it does, to a question that must affect the public health welfare of the whole world.

With the completion of the Panama Canal new routes will be opened up and with them trade relations will be changed between this and other foreign countries. Realising how frequent and extensive is the inter-communication between this country and others affected by dangerous endemic diseases the surprise must be that our country escapes as it does.

The disease above all others which we have cause to fear is plague, and more than one of our cities has been alarmed by a visitation of the dread malady within the past ten years. Fortunately, our domestic sanitation is improving every day, and the mischief-spreading rat is afforded a small opportunity to come into close relationship with human beings. But the appeal which Dr. O'Connell makes for concerted action should not be allowed to rest. There is no cause for alarm, but the policy of leaving well alone can be overdone. The best guarantee for preventing disease is the preparedness of the medical officer of health for eventualities. That is tantamount to saying, "Be prepared for war to maintain peace."

Our Public Health Acts are, generally speaking, far in advance of those of other countries, and one of the powers of these Acts vested in the Local Government Boards is the creation of port sanitary authorities. This power has not been exercised to the extent that one would desire. It was only after plague visited Glasgow that steps were taken to formulate a port sanitary authority for the Clyde. So far as I know there are no other properly constituted port sanitary authorities in Scotland. Yet in the course of the next decade Leith will be converted into a very influential seaport town. At present it is the second largest seaport in Scotland. When plague visited Leith some years ago everything became bustle and confusion. The sanitary authority grudged no expense to rid the port of the incubus of restriction on trade. As soon as the excitement died down and the Local Government Board declared Leith to be free from infection, the administrative charge lapsed into its usual rut.

The sanitary authority, although strongly advised by me to profit by the scare, contented itself by mentally reciting "sufficient unto the day is the evil thereof." This is not as it should be. Sanitary authorities are most susceptible to influence from headquarters, and an official hint that their houses should be put in order would soon achieve the desired result from seaboard sanitary authorities. There is room and need in every one of our large seaports for systematic official inspection and visitation of all ships coming from abroad.

At Leith our oversea grain trade is swelling year by year, and the foreign ports touched include those of all parts of the world. I welcome Dr. O'Connell's letter, and in a cursory way have offered an indication that more can yet be done in this country to strengthen our defences against the assaults of disease. I am, Sir, yours faithfully,

WM. ROBERTSON,
Leith, March 3rd, 1913. Medical Officer of Health.

To the Editor of THE LANCET.

SIR,—The letter of Dr. J. J. O'Connell on the above subject in your issue of March 1st is one of importance and interest. It is a recognised fact that any port which wishes to enjoy a successful maritime trade must keep itself free from cholera, plague, and yellow fever, and it is almost of equal importance to the successful maritime commerce of that port that the ports with which it is in communication are also free.

The Panama Canal, which is happily controlled by the United States, will have the advantage of being supervised by the same sanitary vigilance as the United States exercises in all its great ports. Such extra precautions as may be found to be necessary will be indicated as a consequence of the direct communication opened up between the Pacific and the American ports in the Atlantic. Few, if any, countries have done more, or enjoyed greater success, in the field of sanitation than the United States, and the measures which will be found necessary for its own protection will be the greatest guarantee that the European ports could hope for in the prevention of infection entering the Atlantic *viâ* the Panama Canal.

The visitations of cholera and plague into European countries have not been, as would naturally be expected, increased by more maritime commerce, as indicated by large passenger vessels making long and rapid voyages. The ports infected have been invariably those in the Mediterranean, the infection being due mainly to coasting vessels, the outbreak being as a rule limited in extent. To-day, as in former times, the importation of plague and cholera into Europe would appear to be transmitted along the lines of commerce, such as rivers, railways, caravan routes, or by small coasting steamers. It is by these channels that the outbreaks of importance which have from time to time occurred in Europe have originated.

In recent years the epidemics of cholera in Russia appear to have spread from their endemic centres round the Caspian Sea along the trade routes of the large rivers of Central Russia. The last epidemic in Italy originated by means of small coasting steamers travelling from Asia Minor. Several of the small outbreaks of plague in England have been due to infected rats from tramp steamers arriving from the Black Sea. The chief sources of danger of infection to British ports still appear to be the ports in the Black Sea, the Near Eastern, and the Mediterranean ports.

Last year's International Sanitary Conference at Paris, which had for its object the limitation of cholera, plague, and yellow fever, had a far larger representation from the different States in South America than the Conference of 1903, when Brazil alone sent a delegate. Last year Brazil, Argentina, Bolivia, Chile, Colombia, Ecuador, Paraguay, Panama, and Uruguay were represented. The great object of such Conference is that of mutual protection, and while each port exercises precaution for its own protection against possible invasion by incoming vessels, it has to recognise international obligations by adopting every possible means to ensure that vessels which leave do so under conditions which justify a clean bill of health. By the terms laid down by the Conference each country is expected to supply for the information of other countries notifications of the occurrence of any cases of cholera, plague, or yellow fever, and it remains with the latter to make a declaration for the benefit of their own ports as to whether such notified districts should be regarded as infected.

There is little doubt that the different Governments using the seas connected by the Panama Canal will organise special arrangements for their mutual protection It is difficult to realise that the opening of the Canal will expose Europe to *any increased danger from such diseases as* cholera, plague, and yellow fever Special measures will *need to be taken by the ports in the Atlantic and the* Pacific which are now brought into such close relations by the Canal, and there is no doubt that the combined interests will be quite equal to cope with the altered conditions

I am, Sir, yours faithfully,

R E LAUDER, M D. Durh , F.R C S Edin ,
Medical Officer of Health to the Port of Southampton
Southampton, March 4th, 1913.

To the Editor of THE LANCET.

SIR,—Dr. J J O'Connell's letter in the last issue of THE LANCET advocating the establishment of an elaborate and compulsory system of sanitary inspection and supervision, including quarantine if necessary, of all vessels passing through the Panama Canal, is worthy of serious attention, for if no further serious landslides occur at Cucuracha or upheavals take place in the bottom of the Culebra cutting, the Canal will probably be open for the passage of large vessels early in 1914 Many of the suggestions made by Dr O Connell are admirable, especially the establishment of boarding stations, floating appliances for efficient disinfection, the establishment of isolation hospitals, &c — to these we may add with advantage an abundant and pure supply of drinking water, but a compulsory system [illegible]

Dr O Connell is unduly pessimistic in reference to the dangers of serious epidemics of plague, yellow fever, and cholera, owing to the fact that South American and other danger ports will be brought nearer to some of the American ports *viâ* the Canal The opening of the Suez Canal and the ever increasing speed of passenger and merchant vessels have combined to bring Europe much nearer to the East where these diseases are endemic than obtained formerly, yet the establishment of a stringent system of inspection and quarantine at Suez has never been seriously contemplated in Europe A more thorough knowledge of the natural history of yellow fever, plague, and cholera, and improved sanitation in our ports have combined to reduce the dangers of invasion of these diseases by sea in particular, and England has consistently fought for a reduction of the restrictions to shipping entailed by quarantine regulations and the substitution of the latter by a system of intelligent inspection, removal of infectious individuals to hospitals disinfection and supervision of contacts after arrival in port

Quarantine regulations, if entirely administered by a competent staff of medical men, would probably cause little apprehension to other maritime nations interested in the matter, but as a matter of fact minor lay officials would have to be trusted to a large extent in actual practice, and those who have had much experience in maritime affairs know the weaknesses of the ordinary officials entrusted with such duties in many foreign countries

Dr O Connell states that "political conditions place the *sovereignty over the Canal zone in the hands of the American* Republic Back of all smaller questions now in controversy is the broad and high understanding of all the world, that this sovereignty is not to be exercised for a selfish or a national benefit but for civilisation at large " The action of the American Government in giving preferential treatment to American vessels passing throug i the Canal has unfortunately destroyed the confidence of other nations in the disinterestedness of the former in this matter The establishment of an elaborate system of quarantine regulations, &c , if seriously contemplated is a subject for international discussion in view of the many interests involved, and of the fact that the preventive measures adopted in this country differ so materially from the so called quarantine regulations of most foreign countries

I am, Sir, yours faithfully,

J HOWARD JONES, M.D , D Sc Edin ,
Port Medical Officer of Health, Newport, Mon
Newport March 3rd, 1913

APPENDICITIS: A PLEA FOR IMMEDIATE OPERATION.

To the Editor of THE LANCET

SIR,—At the debate at the Medical Society of London on Feb 10th *we all regretted the absence of Sir George Beatson,* whom we had expected to hear If he had been present he would not have had any doubt as to what I meant by "immediate" operation Had I said "early" operation (as he *suggests), there would have been an opening for uncertainty,* as all people do not put the same meaning to the word Some think that their arrival with luggage at a railway *station is early if it is three minutes before the express is* timed to start, whilst others, to be *early*, like to arrive about an hour beforehand

I used the word ' immediate" because I thought it had a clear and unmistakeable meaning This is what Samuel Johnson says "IMMEDIATE 1 Being in such a state with respect to something else as that there is nothing between *them " (I am sorry that I have not a Scotch dictionary at* hand)

The question for discussion was not as to the *expediency* of doing an operation in any particular or advanced stage of the disease, but one of *principle* These are the words which I used, and by them I stand

> A case of appendicitis should be operated on as soon as ever the diagnosis is *made—within the first 12 hours, if possible—that the patient will then not only* get well, *almost for certain*, but *will get* well very quickly

As your report showed, surgeons came to take part in the debate from widely distant parts of England (and one illustrious surgeon from north of the Tweed), but they all agreed that the only way to make *safe* against surprises, dangers, and fatal results was by operating as soon as the presence of appendicitis is recognised—that is, ' with nothing coming between' the recognition of the disease and the removal of the appendix. [illegible] with every inflamed appendix [illegible] some appear to believe that [illegible] gentler means In my opinion they over estimate their power Time and again a captain may bring his ship securely at high speed through fields of Atlantic ice, but the taking of such a risk is not justified by its success

I am, Sir, yours faithfully,

EDMUND OWEN

Great Cumberland place W , March 3rd, 1913

GASTRO-ENTEROSTOMY IN PERFORATING ULCER

To the Editor of THE LANCET

SIR,—In the paper by Mr Edred Corner on Perforation of Gastric or Duodenal (Pyloric) Ulcers, which appears in THE LANCET of March 1st, pp 600-604, quotations are made from a paper of mine in the Transactions of the Royal Medical and Chirurgical Society (Vol XC , 1907, pp 254–257) which fail to do justice to my views For example, Mr Corner writes "Yet Sir Berkeley Moynihan is not a man to 'say it very deliberately' (his own words) and advise the performance of gastro enterostomy without good reason " The words quoted from me appear in a part of the paper which has nothing to do with gastro enterostomy, but with the absence of shock in the early hours after the perforation of an ulcer. The full sentence is "In the recent cases which I have seen—and I say it very deliberately—there has been no suspicion of shock "

The advocacy by me of the performance of gastro enterostomy in cases of perforated duodenal ulcer dates from 1901, and is contained in a paper published in *THE LANCET of* Dec 14th, 1901, pp 1656–1663 The full paragraph in my paper in the Transactions of the Royal Medical and Chirurgical Society quoted by Mr Corner is as follows

> [illegible] cicatricial contraction of the ulcer, or suspicion of the presence of a second [illegible]

be nearer to the pylorus than the one which has been closed. In those two circumstances only, I think, is gastro-enterostomy justified or compulsory.

In the detailed analysis of my cases which was distributed to the members of the society present at the meeting (loc. cit., p. 395), I say: "If the ulcer be near the pylorus (on either side) and if its closure is at all likely to cause an obstruction; or if a second ulcer be seen in the vicinity of the pylorus, then gastro-enterostomy should be performed; in other cases it is not necessary." A general statement such as Mr. Corner makes to the effect that I advocate the performance of gastro-enterostomy "at the same operation as that at which the ulcer was sutured," is very seriously to misrepresent my meaning. For the differentiation of the two groups of cases, those in which gastro-enterostomy should be done, and those in which it is not necessary, and therefore should on no account be done, is, in my view, of very great importance, and is, I submit, stated in terms of such precision as should make misquotation or misunderstanding impossible. I am, Sir, yours faithfully,

Leeds, March 2nd, 1913. BERKELEY MOYNIHAN.

THE AFTER-EFFECTS OF GASTRO-ENTEROSTOMY.

To the Editor of THE LANCET.

SIR,—The report of the discussion on the After-effects of Gastro-enterostomy at the Surgical Section of the Royal Society of Medicine in your issue of Feb. 22nd, and the paper by Mr. A. W. Bourne in the *British Medical Journal* of March 1st, give one cause for serious inquiry into this subject. These communications tend to shake the confidence of the average surgeon and the profession generally in the efficacy of the operation of gastro-enterostomy, and I do not think that they should be allowed to pass without comment.

During the past fortnight I have communicated with all patients on whom gastro-enterostomy was performed during the year 1909 and during the past 12 months, with the exception of malignant cases, and, of course, of those who died immediately after operation. Previous to 1909 I consider that my operative procedure in these cases was imperfect, hence I think it would serve no good purpose to go back further than that year; but the cases done in 1909 may reasonably enough be looked upon as providing "late" results, while those of the last 12 months provide "immediate" effects. Mr. Bourne's statistics must, of course, be judged from the same standpoint, but at the same time it does not appear from his paper that the technique pursued at St. Mary's Hospital has been altered since 1910. I communicated with 61 patients, and received replies from 53. Six of the remaining 8 had, in the language of the Post Office, "gone and left no address." Of the 53, 49 declared themselves to be absolutely free from symptoms which had existed previous to operation, and, further, had none of the symptoms detailed by Dr. A. F. Hertz, who introduced the discussion at the Royal Society of Medicine. Of the 4 cases who had complaints, 1 was done in 1909. This patient states that, while she is relieved of her stomach symptoms, she has a discharge from the bowel and an occasional swelling in the left iliac region. She is known to be an alcoholic. So far as I can make out her symptoms are due to meso-sigmoid adhesions and accompanying colitis. Of the 2 1912 cases, one complains of occasional "bilious attacks," but is otherwise well; and the other one, who had possibly carcinomatous ulcer which could not be excised, states abruptly that he is not improved and suffers from "pain in the stomach, swelling, cough." This gives a percentage of 5·7 cases (roughly) which are not entirely relieved. Such after-results can surely be due only to the technique of the operative procedure adopted.

In a paper published in THE LANCET of Dec. 3rd, 1910, p. 1610, I drew attention to the principles on which I considered a proper operative procedure should be based, and the only modification of that procedure which I now adopt is the excision of every ulcer when practicable. To recapitulate shortly, I consider that the following are the most important points to attend to: (1) the position and (2) direction of the opening in the stomach (as near the pylorus as possible without causing angulation of the small intestine proximal or distal to the stoma), (3) the size of the opening (I make the opening in the stomach from the lesser to the greater curvature), and (4) the treatment of any extra-gastric abnormality which might possibly have a deleterious reflex action on gastric function. It will be seen that rapid drainage of the stomach is less aimed at than an attempt to make the post-operative conditions conform to normal function. As indicated in my paper referred to, even in so-called atonic stomachs the tone can be restored by appropriate after-treatment, while I find, further, that cases of normal acidity do as well as those with hyperacidity, and cases where no evidence of present or previous ulcer is found do as well as cases where such conditions are present. I believe still what I have previously said[1] that the motor and secretory functions of the cardiac and pyloric parts of the stomach are distinct in action, there being a saccular cardiac portion and a tubular pyloric portion during digestion, which are most distinctly marked the more normal the stomach. The commencement of the pyloric tubular portion is indicated by what I have termed, for the sake of brevity, the "middle sphincter." One should appreciate, in the performance of gastro-enterostomy, the effects of tonicity of the pyloric tube and place the stoma somewhere in it.

Dr. Hertz gives details of "certain unfavourable after-effects" in "many patients" subjected to gastro-enterostomy and afterwards investigated by him. Dr. Hertz (in THE LANCET of Dec. 10th, 1910, p. 1724) criticised very adversely my interpretation of the motor and secretory functions of the stomach on which I base my operative procedures. The results I now publish appear to confirm strongly my interpretation, and should, I think, lead Dr. Hertz to modify the adverse views he then put forward.

I am, Sir, yours faithfully,

Aberdeen, March 3rd, 1913. H. M. W. GRAY.

PHYSICAL CHARACTERISTICS OF MIGRANTS TO THE UNITED STATES.

To the Editor of THE LANCET.

SIR,—In your interesting leading article on this subject in your issue of March 1st, p. 626, it will be noted that there is one characteristic common to the descendants of immigrants of various races—viz., the narrowing of the face. It would be interesting to know whether this narrowing is accompanied by a lengthening of the face; if so, it probably corresponds to a modification of the facial contour which is affecting our population to an enormous extent and which is seemingly associated with adenoid vegetations, nasal stenosis, and mouth-breathing.

The generally accepted hypothesis is that the constantly open mouth puts the muscles on slight tension and thus causes compression of the developing maxillæ, producing the narrow arch. The counter-pressure of the tongue is also lost, as in mouth-breathers the tongue is on the floor of the mouth and does not fill the oral cavity as is the case with normal breathers. This narrowing of the face is accompanied by increased obtuseness of the angle of the mandible, and lengthening of the face.

An annotation which appeared in your columns of Feb. 15th, p. 476, on "Contraction of the Dental Arch and Nasal Stenosis" says that Dr. Matthew Cryer considers that the muscles causing contraction are probably the palato-glossus and the palato-pharyngeus. In this, I think, most people will agree with him. But Dr. Cryer also advances a new hypothesis. He says that the effect of the narrow arch is to compress the tongue and force it back into the oro-pharynx. The tongue "pushes up the soft palate against the post-pharyngeal walls and cuts off respiration through the nose." This seems to me to cut off respiration through the mouth as well; let anyone try the manœuvre for himself. Professor A. Keith considers the alteration of facial contour is only partly caused by mechanical means, and thinks that one or more of the ductless glands are concerned. His article on "Progeria" recently appearing in your columns[2] would seem to confirm this.—I am, Sir, yours faithfully,

Harley-street, W., March 3rd, 1913. WM. RUSHTON.

THE ABDOMINO-PERINEAL OPERATION FOR RECTAL CANCER

To the Editor of THE LANCET

SIR,—In answer to your correspondent Dr R Leonard Ley, writing in THE LANCET of Feb 22nd under the above heading, I should like to point out that he has fallen into one or two errors owing to the fact that he is not acquainted with the more recent developments of this operation In the first place, he considerably over estimates the mortality of the operation in the hands of those who have had some experience in its performance He puts the mortality at 40 per cent This is certainly much too high at the present time, even in non selected cases My own mortality for this operation during the last three years comes out well under 20 per cent , and I have never attempted to select my cases in the sense of choosing those most suitable from a statistical point of view , they have only been selected from the point of view of giving the patient a reasonable chance of cure , and quite half the cases have been men, and a number of them over 60 years of age 45 per cent of my own patients in the last three years have been over 60 years of age and 60 per cent over 55 years of age In an operation of this magnitude, performed as it must necessarily be upon elderly patients usually in a poor state of health, there will always be a serious risk, but with improved technique and experience the mortality has been very much lowered, and my own record would show a still lower mortality had I not had the misfortune to lose two cases from embolism within the last year

Dr Ley states that the chief cause of death from this operation is sepsis I quite agree with him that this was so in the early cases, but it is not now I have only lost one case from sepsis in the last three years, and with careful *technique this danger should be avoided The success of* this operation, as in so many surgical procedures, depends upon the technique, not only of the operation, but also of the preliminary preparation of the patient and the after-treatment of the case, and it is here quite as much as in the actual performance of the operation itself that care and experience tell

I see no advantage in the performance of a preliminary colotomy, and one very serious disadvantage—namely, that there will be grave risk of infection from the colotomy opening at the second operation for the removal of the growth I agree with Dr Ley that the operation should certainly never be performed when the bowel is full of "evil smelling fæces" It is essential that the bowel should be thoroughly cleared out before the operation, but this can be satisfactorily done without having recourse to a preliminary colotomy Of course if the stricture is so tight that there is practically obstruction a colotomy must be performed, but this is seldom the case when it is feasible to remove the growth at all In many cases, especially in women, there is no necessity for a colotomy, it being possible to bring the bowel down, even after extensive resection and thorough clearing out of the glands I do not think that a preliminary colotomy saves much time in the performance of the operation The entire operation in a favourable case—that is to say, in a thin woman, where there is a fairly small growth—can be performed in less than an hour, and this is not an unduly long period I believe the mortality from this operation will be still further reduced as the result of experience and improved technique

I am, Sir, yours faithfully,
P LOCKHART MUMMERY, F R C S Eng

Cavendish place, W March 4th 1913

SUPRARENAL EXTRACT IN GRAVES'S DISEASE

To the Editor of THE LANCET

SIR —Mr James Berry in his lecture on "The Surgery of the Thyroid Gland" asks for evidence in favour of the use of suprarenal extract in Graves's disease as recommended by the late Dr George Gibson May I contribute a fragment? Mrs A has been under treatment at intervals since March, 1910 for Graves's disease with the usual symptoms of moderate severity Improvement was always obtained by a mixture of iron, belladonna and strophanthus In October and November, 1912, however, these remedies entirely failed, and the patient seemed in a serious condition from anæmia and heart weakness I happened to have a bottle of Allen and Hanburys' elixir of suprarenal gland and gave her this with advice to rest I called at her house last week and on inquiry she said . "That was wonderful medicine you gave me I cannot live without it" The evidence which further questions elicited seems as conclusive of cause and effect as such testimony can be —I am, Sir, yours faithfully,

C E H WARREN

Dagnall Park Selhurst S E March 3rd 1913

A POINT IN EXAMINING URINE

To the Editor of THE LANCET

SIR,—When testing urine for sugar we usually add a few drops of urine to the freshly boiled Fehling's solution, and then boil them together But I find that if the urine be poured from a pipette on to the surface of the just boiled Fehling's solution, and the tube be set up for a minute in the test tube rack, we may get a sugar reaction to manifest itself from glucose solutions too dilute to precipitate copper oxide when the test is done in the usual way The oxide forms at the interface and in the urine, where there is little caustic alkali or tartrate to dissolve it This is of interest in examinations for life insurance, and I do not see it chronicled in the usual text-books

I am, Sir, yours faithfully,

THE RELATIONS OF OPERATOR AND ANÆSTHETIST

To the Editor of THE LANCET

SIR,—In a recent leading article[1] in THE LANCET it was pointed out that if any issue ever came to be tried in the law courts involving any question as to the mutual relations of surgeon, anæsthetist, and patient the result must depend upon the ordinary common law applied to the merits and circumstances of the individual case Hitherto, as far as I am aware, the contingencies that might have led to litigation have not done so and if the administration of anæsthetics in dental operations be taken into account it will be appreciated that an enormous number of occasions on which differences of opinion could arise between anæsthetist and operator are characterised by harmonious coöperation in the patient's interest

The most easily to be imagined case in which the relations of an operator, surgical or dental, and an anæsthetist might come to be discussed in a court of law would be an action for negligence brought by a patient Actions for alleged negligence by patients against surgeons or dentists are, of course, not uncommon and a surgeon or dentist if he found himself blamed by a patient might allege that failure on his own part to achieve a successful result was due to something done or omitted by the anæsthetist in connexion with the operation, for which the last-named should rightly be made liable. In any case where the operator ascribed failure on his part to the act of the anæsthetist, but was prepared at the same time to justify that act in the circumstances of the case, and where the anæsthetist accepted the position indicated, a plaintiff would probably have too little chance of success to persevere in his claim. On the other hand, in a case in which the operator was prepared to be a witness on the side of the plaintiff, and in which the issue to be tried was whether the anæsthetist performed his task with a fair, reasonable, and competent degree of skill, the anæsthetist, while admitting that he acted wrongly from the point of view of a prudent or skilful anæsthetist, might allege that he did so under compulsion exercised by the operator. The anæsthetist will, of course, be liable for any default of his own committing, and it would not be easy for him in such a case as is here imagined to shift the responsibility.

---

[1] THE LANCET Dec 7th 1912 p 1599

The anæsthetist could hardly be held on any such occasion to be subject to the orders of the operator, so as to deprive him of his position of responsibility to the patient. His relation to the patient is similar to that of the operator, who very generally introduces him, but who, provided that he exercises reasonable care in doing so, cannot be deemed to incur any legal liability for the conduct by his colleague of his particular share in the operation.

We may turn from actions for negligence brought by patients to consider whether any other occasion might produce litigation involving the relations between an operator and anæsthetist. We may imagine special arrangements to have been made between an operator (a surgeon or a dentist) and an anæsthetist to work together. Under such a contract the mutual relations of the two parties might be defined and might differ from those which I have suggested above, so that either of them might be found suing the other for an alleged breach of an agreement to perform certain duties in a certain way.

I am, Sir, yours faithfully,

Feb. 24th, 1912. Jurisprudentia.

⁎⁎⁎ We do not think that such an arrangement is either likely to be met with or desirable. The cordial understanding between operator and anæsthetist necessary for the efficient performance of their respective shares in acts of grave importance to a third person will it is to be hoped long continue to prevent any possible differences of opinion between individual members of two branches of the same profession from being ventilated in courts of law.—Ed. L.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of The Lancet.

Sir,—Your correspondent Dr. D. J. Munro brings forward the pledge. I confess that I wished and thought the pledge was dead. I remain under the impression that it died a natural death when the report of the Advisory Committee appeared, and that the Representatives occupied Jan. 17th and 18th in writing out the death certificate. When he says he is bound by the pledge he is in error, for he is in reality bound by the conviction that the terms and conditions of service are not satisfactory. With wider knowledge and after much thought I have arrived at the opposite conclusion. There are two parties diametrically opposed to each other. The terms of the pledge, therefore, are impossible of accomplishment—"satisfactory to the whole profession." A compromise has been arrived at to give the Act a fair trial for three years. The resolution of the British Medical Association prepares the way. Those who think well of the Act are at liberty to accept it without any feeling that they are disloyal. Those who are of the other opinion are equally at liberty to refrain, or to experiment and save themselves from being ousted out of a portion of their income. Dr. Munro shivers with horror at the "panel system." His name has been on a panel of qualified practitioners for a dozen years. It is asserted that the majority of the metropolitan practitioners are opposed to the Act. I knew that five years ago. They are not "die-hards," but "do-nothings," "pigheads," ready to "brand" with a "stigma" anyone who does not happen to agree with them at the moment. My letter was not based on any assumption that the Act was right or wrong; it is a question of ethics.

With regard to the handbills, three men are directly responsible; all are members of the Association and, I think, Licentiates of the College of Physicians. Among the 77 or 80 doctors on the Kensington panel at the time (I limit myself to Kensington) were undoubtedly some members of the Association. As yet there is no sign of the Central Ethical Committee taking the matter in hand. Until my questions are answered no doctor on the panel can regard himself as under any obligation to the Association.

Will the College of Physicians endorse the conduct of its Licentiates?—I am, Sir, yours faithfully,

George Crichton, M.D. Edin.

Longridge-road, South Kensington, Feb. 25th, 1913.

THE NATIONAL MEDICAL UNION.

To the Editor of The Lancet.

Sir,—It has come to the knowledge of the executive committee of the National Medical Union that misleading statements as to the methods and objects of this association have appeared in many newspapers during the last few weeks throughout the country. These statements must have been founded on a mistake, the authors having confused the aim of two separate societies, the names of which are somewhat similar.

The National Medical Union has been in existence for nearly 15 months, and is well known. The National Medical Guild is a new body which has been lately originated in London, and which is now making application for recognition as a trades union. The National Medical Union as constituted at present is a society composed exclusively of medical men who do not intend to take service of any kind under the National Insurance Act as it now stands after April 14th, 1913. The Union exists primarily for the interests of these men. It has no intention of working on trades union lines. It aims at uniting "non-panel" men all over the country, at furthering their interests, and at defending their rights; it seeks to preserve the honour, independence, and efficiency of the profession; and it hopes to form a "rallying ground" for doctors who, having accepted service on panels and found out the impossibility of doing sound work thereon, are desirous of retiring therefrom.

The Union will work for the provision of adequate medical attendance for the industrial classes at reasonable remuneration on the lines of general practice, and it will seek for such amendment of the National Insurance Act as will secure this and safeguard the interests of both patients and doctor. The National Medical Union, whilst sympathising with the general attitude of the National Medical Guild, is not at the present time in favour of the promotion of their common aims by trades union methods.

We are, Sir, yours faithfully

G. A. Wright, President.
William Coates, Chairman.
J. Webster Watts, Secretary.
E. W. Floyd } Honorary
J. Skardon Prowse } Secretaries.

Donations and Bequests.—The late Lord Ilkeston has left £800 on trust for the foundation of a scholarship at the University of Durham in memory of his late daughter, Winifred Foster, who was a student there, the income to be applied to a "Winifred Foster Scholarship," to be awarded to a woman student who requires help to maintain herself at the University, and shall be a student and reside at such University, and who shall have taken a sufficiently high place in the matriculation examination and be under the age of 22 years.—Subject to a life interest, the late Mr. D. M. Forbes, medical officer of health for the Eastwood urban district council, Notts, has left by will £1000 to the Nottingham General Hospital and £500 to the Eastwood Nursing Association.—Sir Gilbert Wills, M.P., and his family have offered £5000 in memory of the late Sir Frederick Wills to the Royal Victoria and West Hants Hospital, Bournemouth, towards the building of an administration block at the Boscombe branch of the hospital.—An anonymous donor has promised a gift of £10,000 to the Middlesex Hospital.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

I.—THE STRUGGLE AT SOUTHAMPTON.

Professional Harmony.

THE time is now at hand when we may leave the realms of theoretical controversy and approach more certain ground. We are no longer facing solely a question of the good or ill that may result from the National Insurance Act. To-day the new law is in active operation, and therefore it is already possible to note and record some of the consequences that are becoming manifest. To do this throughout the country in an exhaustive manner would obviously be impossible; the conditions of medical practice vary considerably from locality to locality, and the hardship of one place may weigh lightly in another, while the grave abuse in a northern county may not have its counterpart in the south. To study the working of the Act and gauge what effect it is producing in real practice I selected Southampton for my first investigation, because both the medical profession, on one side, and the population affected by the Act, on the other side, are exceptionally well organised. More than once there has been occasion to describe the admirable sense of union which has brought the vast majority of practitioners at Southampton together so as to deal with the evils that result from contract practice. On the other hand, the great friendly or benefit societies and the trades unions are very numerous and powerful at Southampton. How the medical practitioners of this port formed a provident medical association has been related in these pages, and early in the discussion on the Insurance Bill it was suggested that this organisation might be used as the medium for the administration of the medical benefits under this scheme, should the Bill become law.[1] Later in the day, however, it was evident that greater unanimity in the profession would have to be secured. The Provident Medical Association, for instance, was frankly opposed to the four medical men whom the Federation of Friendly Societies had imported and to whom they paid regular salaries for their full time. But when it became a question of fighting the Government it was felt that all such minor quarrels and differences must be set aside so as to secure absolutely united action. A provisional local medical committee was formed with its doors open wide to all. Instead of ostracising them, special overtures were made to the club officers, and when they consented to fall into line with all the other members of the profession their presence was particularly welcomed. This generous and broad policy was fully justified by the events, for these practitioners, who had known what it felt to be called "blacklegs," proved better fighters in action and more staunch to the medical union than several of its oldest members. The proposal was that if the Bill were modified in the sense desired by the medical men, and in accordance with the generally expressed medical policy, then the provisional committee thus formed would become the permanent Local Medical Committee under the Act. Nor has the last word been said; for, in spite of the disappointments that have ensued, this policy may yet be brought about. Having united the entire local profession, including the club doctors with whom they were formerly in conflict, the provisional local medical committee determined to stand out and refuse to go on the panel. To make quite sure of fidelity to the cause, one of the medical men who was employed by the Federation of the Benefit or Friendly Societies was elected on a committee consisting of 15 members appointed to carry on negotiations. Yet his interest in going on the panel was greater than that of most of the Southampton practitioners. He ran the risk of enormous loss by standing out. Nevertheless, he was quite ready to incur this risk. Such harmony in the medical profession had never been known before in Southampton. It was then said that whatever else the Act might do, its discussion had engendered a spirit of union among practitioners stronger, more unanimous, and more widely spread, than anything shown in previous struggles. Every practitioner in the borough had been tested; they had all gone through an ordeal which had proved who could be trusted, and everything gave good promise of victory in the approaching fight. The old Southampton Provident Medical Association formed by the Medical Union was converted into the Public Medical Service to which all the practitioners were attached, and through which it was proposed to treat insured persons and to include the uninsured relatives and dependents that were not included in the scope of the Act.

The Betrayal.

A great [illegible], was in store. I am informed [illegible] single influential man caused all [illegible] to collapse. On the Sunday preceding Jan. 1st, first one, then another, then two or three medical practitioners together, went about asking their colleagues whether they would go on the panel if a panel was formed. In the circumstance, such a question indicated hesitation, and as the instigator of surrender was a member of the committee of 15 a panic was caused. Three or four practitioners were so alarmed that they at once enrolled themselves on the panel, and the united front which the profession had so bravely shown up to this date was broken. Doubtful as to what might follow, the fight on the lines at first intended had to be abandoned, and the action of the medical profession was entirely reversed. Instead of refusing to join the panel, it was decided practically to swamp the panel, and to-day no less than 45 practitioners have inscribed their names. Of course, the reversal of policy was a great disappointment to those who had pinned their faith upon professional solidarity, and it has inevitably lowered the medical profession in the eyes of some of those whose esteem it is important to maintain, and who have seen only the alteration of tactics and have understood little or nothing of the pressure that has been brought to bear on the medical profession. The organised working classes were quite disposed to sympathise with the medical profession had its members continued a plucky fight. As it is, some of their leaders have not hesitated to sneer at the strike-breakers, although the Public Medical Service was attempting to obtain terms which to some extent militated against the interests of the workmen.

An Ideal Arrangement Realised.

This is the more unfortunate as the object now held in view by many practitioners is to establish a widely and easily applied system of contracting out of the Act so far as the medical service is concerned. But this can never be [illegible] the insured [illegible] efit societies [illegible] lies; and it is through the action of one of the latter, the Seafarers' Union, that almost ideal conditions have been secured for one branch of the work at Southampton. Here the majority of the Seamen's National Insurance Society belong to this very active and bellicose trade union. Their insurance society under Clause 48 of the Act is empowered to make its own regulations in regard to medical service. This society, in its national capacity, decided to appoint in the various ports where it has branches a few selected medical officers to attend those members who fell ill when on shore. But at Southampton they could not do this: the profession was too well organised. It was not possible to apply to individual practitioners, for these latter with great discipline referred the applicants to the Southampton Public Medical Service. The latter is, of course, in favour of the free choice of medical adviser, and would not hear of the proposal to force upon the members of the Seamen's National Insurance Society a choice of medical attendants restricted to five or six specially selected doctors. Besides, who was to make the selection and on what principle would it be made? The Insurance Society's managing committee would naturally have liked to make this selection themselves. It would have added to their importance by enabling them to exercise a piece of patronage, but their argument is that they could better control the medical men on whom they bestowed a remunerative preference. Medical practitioners, however, objected to be controlled by committees of working men; the only control they admit is that [illegible] is *really concerned—namely*, t[illegible] their professional conduct is [illegible] unwritten law of professiona[illegible] medical profession claims for the patient the right both to select and to change his medical adviser till he has found someone in whom he has full confidence. Thus it came about that the Seamen's National Insurance Society at Southampton has not been able to secure the services of five or six medical officers; but a much better solution of the difficulty has been forced upon them. They have had to accept the principle of the free choice of medical adviser, and their members can now call upon any of the 60 or so members of the Public Medical Service. They are thus better off than many insured persons who can only choose from the medical men inscribed on a smaller panel. The seamen, therefore, obtain the services of the practitioners who are on the panel and those who are not on the panel; and if any complaint should arise it would be for the entire profession, and not merely a portion of the profession, to deal with it. Then the difficulty that arises when the medical attendant of the wife and family is not on the panel and the insured bread-winner has to call in another, and to him, unknown practitioner, is removed. Every practitioner belongs to the Public Medical Service, though they are not, of course, all on the panel.

---

[1] See THE LANCET of Feb. 13th, 1904, article on "The Battle of the Clubs," and June 24th, 1911, p. 1731.

The Giving of Unnecessary Offence.

A satisfactory arrangement having thus been made with one important labour organisation, one is bound to ask if this example could not be extended to other similar bodies? The fact that Clause 48 of the Act only applies to a few organisations constitutes a negative reply; but much could be done if good-will was displayed on both sides. Unfortunately, my Southampton experience tends to show that a good many medical men have injured their position and opportunities by expressions and conversations which have displayed more prejudice than sagacity. Considering the large share of representation and influence that the organised working class must exercise on the County or Borough Insurance Committee, it is absolutely foolish to give unnecessary offence to the working-class leaders. It has been my good fortune to have personal intercourse with many of the most influential popular leaders, and I cannot render a better service to all parties concerned than to deprecate words spoken on either side which may produce unnecessary and unwarranted friction. It seems to me that in the present state of affairs medical men in particular should measure their language. Thus the opinion has been expressed in Southampton that there were men who would squander in drink the 30*s.* maternity grant given to their wives. Doubtless there may be a few such selfish brutes, but males of this order are not confined exclusively to the working class. In my experience it is in the poorest sections of the community that the greatest readiness and generosity are displayed in helping each other in moments of sickness and difficulty.

The Question of Control.

Nor will any good be achieved if medical men adopt an attitude in regard to lay management which in the event proves a wrong one. To quote the words of a prominent labour leader on the Southampton Borough Insurance Committee: "It is absurd," he said, "to suppose that laymen had any idea whatsoever of exercising a technical control." But, he continued, they could discuss such simple matters as carelessness in giving advice. As elected members on the Insurance Committee it was their duty to maintain the powers the Act had conferred upon them so as to prevent, and if possible to punish, gross incompetence and neglect. A lady member of the Insurance Committee who, being also a member of the board of guardians, knew something of the condition of the poor, gladly—in fact, enthusiastically—recognised that as a rule the medical practitioners of Southampton did their best for their patients, and that there was no fault to find. But there were exceptions even in Southampton, as all knew full well. Besides, a tribunal was needed to judge matters not solely from the point of view of the medical profession, for the public was equally concerned in the safeguarding of its interests. Under these circumstances it was urged that there was no other course open than that of making the best use possible of the Borough and County Insurance Committees and the Medical Service Subcommittees. But the control was to be a business and administrative control, and would not interfere with scientific and technical matters.

(*To be continued.*)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New Lecturer in Mental Diseases at the University of Liverpool.

THE Council of the University at its meeting held on Feb. 25th appointed Dr. T. P. Cowen, medical superintendent of the County Asylum, Rainhill, to the lectureship in mental diseases rendered vacant by the resignation of Dr. Joseph Wiglesworth, late medical superintendent of Rainhill County Asylum.

University of Liverpool: Proposed Veterinary Hospital.

Professor Ernest E. Glynn, who was recently appointed to the chair of pathology at the University in succession to the late Sir Rubert Boyce, delivered a public inaugural lecture on Feb. 21st on the Study of Disease in Domesticated Animals. He strongly advocated the addition of a veterinary hospital to the School of Veterinary Science in Liverpool.

David Lewis Northern Hospital.

A special service in aid of the funds of the above hospital was held on Sunday, March 2nd, at St. Luke's Church. The Lord Mayor and members of the city council attended in state. The sermon was preached by Archdeacon Fletcher, of Chorley. The service was also attended by members of the committee and several of the honorary medical staff of the hospital. The collection realised £61.

March 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Certificates under the National Insurance Act.

A SUM of £50,000 has been given Ireland towards the cost of medical certificates of sickness and other expenses of administration, owing to the absence of medical benefit in Ireland, and at present negotiations are going on between the Conjoint Committee and the Insurance Commissioners as to the rate of payment for certificates. Both parties have agreed to the principle of remuneration based on a capitation rate, and that a sum representing a penny per insured person should be deducted from the £50,000 to defray expenses of administration by Insurance Committees, and a further limited amount for payment to hospitals in respect of certificates given to out-patients. The Commissioners have submitted for the consideration of the Conjoint Committee three schemes; in the first there are three broad divisions (the capitation rates in which would be 1*s.*, 2*s.*, and 1*s.* 2*d.*): (1) six county boroughs (Dublin, Belfast, Cork, Limerick, Londonderry, and Waterford); (2) the most inaccessible areas; and (3) other parts of Ireland. In scheme No. 2 there are four classes, the respective rates being 9*d.*, 2*s.*, 1*s.* 4*d.*, and 1*s.* 6*d.*—namely, (1) the six county boroughs and towns of over 10,000 population; (2) the most inaccessible areas; (3) the counties with a net acreage per person of less than 7; (4) the counties with a net acreage per person of 7 and upwards. In scheme No. 3 Ireland is divided into four classes as follows (the respective capitation rates being 10*d.*, 2*s.*, 1*s.* 3*d.*, and 1*s.* 6*d.*): (1) the six county boroughs and towns of over 10,000 population; (2) the most inaccessible areas; (3) the counties with a net acreage per person of less than 7; (4) the counties with a net acreage per person of 7 and upwards. It is assumed that in Ireland there will be 750,000 insured persons. The Commissioners also offer for consideration a capitation fee of 4½*d.* (exclusive of drugs) for the domiciliary treatment of insured persons suffering from tuberculosis, this rate to be in addition to the capitation rate for medical certification.

Maternity Benefit in Ireland.

A conference of Approved Soc [illegible] by the Irish National Health Insurance [illegible] the Gresham Hotel, Dublin, on Fe [illegible] considering the administration of [illegible] arranging a basis of fees betwee [illegible] midwives, and insured persons. [illegible] mission (Mr. J. A. Glynn), who presided, in the course of an address, made several suggestions to the representatives of the societies. In opposition to the view of the Local

Government Board that only in exceptional cases might attendance on a patient entitled to the maternity benefit be given under the Medical Charities Act, Mr. Glynn held that only in exceptional cases should a fee be paid to either medical man or midwife. With regard to the fee that ought to be paid, the chairman said that, having considered the matter carefully and obtained the best advice possible, the Commissioners thought that the fee for the doctor should be 7*s.* 6*d.*, or for the nurse 5*s.* In Wales 15*s.* had been agreed upon as a suitable fee for the attendance of a medical man, but he thought such a fee too high in Ireland. He further declared that the Commissioners would approach the Local Government Board with a view of getting societies and boards of guardians to agree as to the class of case for which tickets might be issued under the Medical Charities Act. Resolutions in accordance with these views were passed unanimously. Mr. Glynn's proposals will certainly not be acceptable to the medical profession, and it is very unlikely that any medical man will be persuaded to work for the miserable fees offered. The decision as to what patients may rightly be attended as "poor persons" under the Medical Charities Act is a matter for individual guardians under advice from the Local Government Board and subject to correction by the courts. The Local Government Board a few weeks ago issued a circular letter dealing with the question, and it is entirely outside the purview of the Insurance Commissioners. In making a suggestion as to a suitable confinement fee, Mr. Glynn declared that the Commission had obtained "the best advice possible." It is noteworthy that neither the medical nor nursing members of the Advisory Committee were consulted, nor was the Conjoint Committee as representing the medical profession. The suggestion that the fee in Ireland should be only half that in Wales is monstrous, in view of the much greater distances that have to be travelled in rural Ireland. £1 is, as a matter of fact, the usual confinement fee paid at present among the industrial classes in the North of Ireland. If the societies agree to Mr. Glynn's suggestion as to the maximum maternity fee they should pay, only one result can follow—the handing over of midwifery practice in Ireland to the cheapest and worst of midwives and to handywomen. For such an event the Commissioners must take the full responsibility.

The Medical Benefit Committee

The committee appointed by Mr. Lloyd George to inquire into the question of the advisability of extending medical benefit to Ireland met in Belfast on March 4th. The committee has refused to hear evidence from Poor-law bodies (though the question of Poor-law administration must be considered), from hospital authorities (although medical benefit without provision for institutional treatment in hospitals is useless), and from the local medical profession. Instead it will hear one person nominated by the conjoint committee to represent many diverse interests. It has [illegible], the Friendly Societies asking [illegible] such representative bodies as [illegible] the *Linen Merchants' Association* have declined the invitation on the ground that such benefits are not needed in Ireland, since similar benefits are already available, and that the inclusion of Ireland would involve additional cost to the community without compensating results. Rightly or wrongly, the general feeling is that a scheme is already arranged and that the hearing of evidence is a mere placebo to the public, and that on Jan. 1st, 1914, medical benefit will be in existence in Ireland.

Belfast Practitioners and the Medical Benefit Committee.

At a largely attended meeting of the medical profession of Belfast and district held in the Medical Institute on Feb. 27th, a resolution was passed unanimously expressing regret and surprise that the Committee on Medical Benefits had refused to hear the members selected on Feb. 13th by the local practitioners to give evidence. The meeting again tendered the names of the medical witnesses, and urged that it was essential that they be heard, as representing the various views of medical men in the largest industrial centre of Ireland. The meeting also urged the committee to receive evidence from practitioners in other urban and rural areas of the North of Ireland.

Presentation to Dr. George Sigerson.

The friends and admirers of Dr. George Sigerson met last week to present him with a portrait of himself, by Mr. J. Lavery, as a token of their esteem. Dr. Sigerson has been professor of biology in University College, Dublin, for a great many years, and, apart from his medical work, has gained distinction as a poet and a Gaelic scholar.

March 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Association Internationale de Perfectionnement Scientifique et Médical.

THE annual general meeting of this association will take place at the end of May, under the presidency of M. Aristide Briand, President of the Council and Minister of the Interior, when the following medals of honour will be presented: the medal for Social Service (*du Bien Social*) to Her Majesty the Queen of the Belgians; the medal for Scientific Merit to Professor Armand Gautier; and the Association medal to Professor Ehlers, of Copenhagen. Cards of admission can be obtained by writing (enclosing postage for reply) to the President of the A.P.M., 12, Rue François Millet, Paris XVI.

The Degree of Doctor of Medicine.

I have already referred to certain resolutions carried at the meeting of the Superior Council of Public Instruction The council has also decided to increase the fees. Under the present *régime*, which dates back to 1893, the fees amount to 1395 francs. They are now to be increased by 245 francs to a total of 1640 francs, of which 950 francs will go to the universities and 600 to the Treasury.

The Treatment of Peritoneal Infection by Ether.

M. Souligoux stated at the Société de Chirurgie on Feb. 19th that he used ether habitually in the treatment of infections generally, and that it could be used to special advantage in peritoneal infections. Last July M. Souligoux saw a woman who had been attacked eight days previously with intestinal obstruction, and who presented abrupt signs of peritonitis with fæcal vomiting and fever. M. Souligoux did not see her until some little time after the onset, and as he diagnosed a rectal stenosis he decided to make an artificial anus in the iliac region. On making the incision, however, a perforation of the intestine was found, filling the abdomen with fæcal material. He closed the perforation, which was in the cæcum, washed out the abdomen with ether, and made an artificial anus, and the patient, much to the general surprise, made a perfect recovery. M. Souligoux has since that time always used ether in peritoneal infections.

The Notification of Infectious Diseases.

M. Doizy, the Deputy for the Ardennes and a member of the Parliamentary Commission on Hygiene, expounded recently to the members of the Société de Médecine Publique et de Génie Sanitaire the defects and the qualities of the law for the protection of the public health. He stated that the notifications of transmissible diseases now being made by medical men in accordance with this law amounted to over 100,000 per annum, while at first they numbered only a few thousands, showing a comparative progress in the practice of notification. He concluded by demanding that the head of the family should be made responsible for the notification, and that a post of inspector or departmental director should be established, upon whom should devolve the carrying out of the sanitary laws.

The Morbidity and Mortality of Diphtheria.

At the last meeting of the Société Médicale des Hôpitaux M. D. Martin said that up to the present Paris and France showed the best statistics in regard to diphtheria. He considered it important to demonstrate this fact by figures. For Paris, in the 14 years (1880 to 1893 inclusive) preceding the introduction of antidiphtheritic serum therapy, the mean annual mortality was 1721 deaths, with a maximum of 2244 in 1882, and a minimum of 1266 in 1890. In the 15 years subsequent to the introduction of serum therapy the annual mean was 348 deaths, with a maximum of 736 in 1901 and a minimum of 174 in 1906. In 1896 the morbidity diminished, yet the mortality increased, following on a statement in 1895 by M. Moizard that in a case of non-diphtheritic angina treated by the serum death had ensued, from which fact both medical men and the public had concluded that the use of the serum was dangerous

The Disinfection of Crèches.

On the motion of M. Poirier, of Narçay, the Conseil Général de la Seine passed a resolution proposed by M. Ambroise Rendu that the council's grant should be restricted to those crèches in the department which possessed disinfecting apparatus for the children's clothes. It further decreed that, except in the case of crèches unprovided with such disinfecting apparatus, the grant should be withdrawn only after consultation with the Conseil Général.

The Treatment of Amœbic Dysentery.

M. Chauffard recently drew the attention of the Academy of Medicine to the Emetine treatment in amœbic dysentery. M. Chauffard had recently treated by this method with very good results a man who had a dysenteric abscess of the liver communicating with the bronchial tree. At the time of beginning the treatment the hepato-bronchial fistula had existed for five months. From 200 to 250 c.c. of reddish purulent material was being evacuated daily, the rectum was ulcerated, the general condition was very poor, and radioscopic examination showed an extensive opacity at the base of the right lung and merging into the hepatic opacity. Between Dec. 21st and 25th the patient received six injections, each of 4 centigrammes of emetine hydrochloride, which were well borne. The expectoration dropped from 200 c.c. to 150 c.c. on the first day, 60 c.c. on the second, and 45 c.c. on the fourth. On the fifth day the patient expectorated only three times, and since then there had been no expectoration. The temperature also fell below 98·6° F. and there remained. The leucocytosis dropped from 49,000 to 19,800, the polynuclear count from 77 to 63. The rectal ulceration had cicatrised and the base of the right lung had become clear. The patient was thus completely cured and had gained nearly 6 kilogrammes in weight.

March 3rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Regulations Concerning the Sale of Food.

NEW regulations concerning the preparation of food in shops and warehouses and its subsequent sale have been lately issued by the Federal Council. The tradesmen chiefly affected are bakers, butchers, grocers, and others engaged in the sale of articles of food. According to the regulations, the places where food is sold or prepared must be clean, dry, and well ventilated. They must not be used as sleeping or sitting rooms, and beds, clothes, linen, and rubbish must not be kept in them. Dogs and cats must not stay in those parts of the premises, and customers must be warned against bringing these animals with them. The floors of places where meat and fruit are sold must admit of being washed. Raw meat carried through the street must be covered with a clean cloth. Persons engaged in the preparation or the sale of food may neither smoke, nor take snuff, nor chew tobacco while at work. Employers are required to provide adequate washing arrangements and a sufficient number of towels. The public is warned against handling meat, fish, bread, pastry, or fruit offered for sale. The police are authorised to enforce observance of the above regulations, and offenders are liable to a fine not exceeding 60 marks (£3).

Medicine and Music.

More than a year ago an orchestra was formed in Berlin consisting of medical men residing in that city, and the circumstance was duly noted in THE LANCET, vol. ii., 1911, p. 263. A further movement in the same direction is now about to be made by the formation of a choral society consisting exclusively of medical men and members of their families. The interest which the profession takes in the matter is shown by the fact that at the inaugural meeting 34 medical men and 37 ladies were enrolled as members. The president is Dr. Singer, a very appropriate name for the occupant of a position in connexion with a choral society.

Jubilee of the Höchster Farbwerke.

The well-known Höchster Farbwerke, one of the largest chemical works in Germany and indeed in Europe, has lately celebrated its jubilee. In a Festschrift published by the firm some interesting particulars are reported with respect to its production of pharmaceutical preparations. The manufacture of such preparations began only in the year 1883, and the first of these substances which was put upon the market—kairine, an antipyretic compound intended to replace quinine—turned out to be a failure. The second one, however, was antipyrine, which has had an immense sale, continuing with little interruption up to the present time. The factory was afterwards engaged in the manufacture of anti-bacterial remedies, beginning with Professor Koch's tuberculin and Professor Behring's antidiphtheria serum. It deserves to be mentioned that the firm gave financial support to the experiments of Professor Behring when he was unable for want of funds to continue them, and when it was still quite uncertain whether the experiments would lead to a practical result. The synthesis of suprarenin was another of the successes achieved by the Höchst factory. One of its most recent productions is generally known as salvarsan, and was introduced by Professor Ehrlich, whose experiments leading up to its discovery also, I am informed, received financial assistance from the firm.

Congress on Physiotherapy.

An International Congress on Physiotherapy will be held in Berlin from March 26th to the 30th under the patronage of H.R.H. Prince August Wilhelm of Prussia, Doctor of Laws. The presidents are Professor His and Professor Brieger, of Berlin. The principal subject of discussion will be the treatment of disorders of the circulation. The work of the congress will be divided into four sections—namely, (1) Hydro-, Balneo-, and Climatotherapy, introduced by Professor Brieger; (2) Electro- and Radiotherapy, introduced by Professor Oppenheim, Dr. Bickel, and Professor Levy-Dorn; (3) Orthopædy, introduced by Professor Joachimsthal; and (4) Dietetic Treatment, introduced by Professor Strauss. The honorary general secretary is Dr. Immelmann, Lützow-strasse 72. An exhibition of objects of interest will be formed in connexion with the congress. The medical profession of Berlin will entertain the members of the congress at a conversazione. The programme includes a concert and a "cabaret," in which all the performers will be medical men and their wives.

Statistics of Suicide.

The number of suicides in Prussia showed a slight decrease during the year 1911, when 21 cases were registered for each 100,000 of the population, as compared with 22 in 1910. The actual number of persons who took their own lives was 8422, of whom 6394 were men and 2028 were women. The relatively highest proportion of suicides—namely, 35 for each 100,000—occurred in the province of Brandenburg; next came Berlin with 32 per 100,000. The tendency to commit suicide increases with the age, the proportion per 100,000 at various age periods being as follows: between 15 and 25 years, 17; between 20 and 25 years, 25; between 30 and 40 years, 23; between 60 and 70 years, 52; between 70 and 80 years, 61; and over 80 years, 63. The causes of suicide especially in advanced age are not always very clear. About 25 per cent. of suicides are said to be caused by insanity. In 879 cases bodily suffering, in 600 cases alcoholic excess, in 942 cases sorrow, and in 604 cases remorse were the causes assigned. In 1786 cases the cause was absolutely unknown. It is remarkable that certain days of the week showed a greater number of suicides than others. The smallest number of suicides happened on Fridays and Sundays, and the highest number on Mondays and Tuesdays.

Society for Sexual Science.

A new medical society for the study of sexual science has been formed in Berlin, the provisional committee including Professor Eulenburg, Dr. Magnus Hirschfeld, Dr. Koerber, Dr. Iwan Bloch, and others. The objects of the new society are the investigation of the sexual life according to scientific principles and the promotion of interest in these researches among the medical profession. Ordinary membership is reserved to medical men and medical women exclusively; members of other professions are eligible as extraordinary members. At the inaugural meeting Dr. Bloch will read an address on the future work of the society, and Dr. Hirschfeld will show wax casts of hermaphrodites. In the subsequent meetings papers will be read by Professor Eulenburg on sexual neurasthenia, by Dr Burchard on sexual infantilismus, by Dr Adler on the frigidity of women, and by Dr Rohleder on artificial impregnation.

NOTES FROM SOUTH AFRICA

(FROM OUR OWN CORRESPONDENT.)

Cape Medical Council Election

THE triennial election for the Cape Medical Council has just been held, resulting in the return of Dr W Darley Hartley, Dr John Hewat, M L A, Dr A J Gregory, and Dr D J Wood. On all matters of medical policy the candidates were more or less in complete agreement, and the election was decided mainly on personal issues. But a regrettable feature of the election was a series of scurrilous letters that were published locally attacking Dr A J Gregory with a view of detaching votes from his candidature. His return to the Cape Medical Council, on which for many years he was, as medical officer of health for the colony, an *ex officio* member, is particularly welcome, in view of the fact that that body probably will have to criticise on behalf of the profession, before its term of office expires, not only the Draft Union Medical Bill, but also any proposed public health legislation.

South African Order of Nurses

During the last few months the committee appointed to promote Lady Gladstone's scheme for inaugurating a South African Order of Nurses in commemoration of the reign of King Edward VII has been exceptionally busy. A number of meetings have been held and draft regulations prepared. Miss Childe, matron of the Government Hospital, Maseru, Basutoland, has been appointed organising matron, subject to the consent of the Government of Basutoland. The committee has been actively canvassing for funds from the public, and during the past three months street collections have been held in all the principal towns in the Union, but the response has by no means been as generous as might reasonably have been expected, and the total funds available are not likely to exceed £15,000. The fact is that South Africa is very lukewarm with regard to the scheme itself. The main reason for the apathy displayed would seem to be that the public does not realise properly the exact objects of the scheme. The large towns, where the strongest appeal for support has been made, are, on the whole, fairly well equipped with nurses and with hospitals, and their inhabitants have in a sense resented being asked to put their hands in their pockets to assist people less fortunately situated elsewhere. Again, the medical profession is perhaps even more lukewarm than the general public in support of the scheme. The profession did not wish the memorial to take its existing form and would have preferred a sanatorium for consumptives. It even perhaps regards with a certain amount of suspicion the proposal to send nurses out into the country districts. Again, nurses in private practice are generally hostile to the scheme through fear of competition. Had the memorial taken the form of a sanatorium for consumptives, doubtless the movement would have been accorded the warm support of the medical and nursing professions, and had this been secured the response to the appeal would have been infinitely more generous. It is true that a considerable section of the community do not see any necessity for a memorial to be established at all. The Afrikander farmer in particular has been quite *apathetic, if not actually hostile, although it is mainly* for the benefit of this class that the present scheme is being inaugurated. In most cases this is not due to lack of loyalty, but because the idea of voluntarily subscribing anything except in support of the Church is foreign to this section of the community. This is well exemplified by the memorial fund raised in connexion with the late Jan Hofmeyr, for many years the leading politician in South Africa, which closed recently at £1600, after being open for some two years and after every effort had been made by the leaders of the Bond to induce the members of that organisation to give freely to the memorial instituted in honour of its founder. The amounts received for the Order of Nurses have been collected almost entirely from the inhabitants of the towns, and, though the response has been generally dis- [illegible]

[illegible] South Africa is insufficient for the hospitals of the country and for the requirements of ordinary private practice in the towns. It would, therefore, seem likely that the Committee will find great difficulty in obtaining trained nurses of any sort, and that it will be unable to demand of them that they know the two languages. It will be necessary for the nurses who join the Order to be stationed in small villages, and they will have to carry on their work for the most part on farms amid the primitive and comfortless surroundings of the backveld. It is probable that nurses, who have hitherto been in a position to pick and choose their work to a large extent owing to the demand exceeding the supply, will not be willing to join the Order unless they are offered high salaries. The shortage of nurses is indeed a serious problem to be faced by everyone. The number of institutions is rapidly expanding, whilst the medical councils have in recent years struck off the list a number of training schools altogether, and in certain of the others extended the curriculum to such an extent that it is practically impossible for the managers to recruit probationers. The prospects of the scheme at the moment do not appear rosy.

South African Defence Act

A most extraordinary circular has recently been issued to resident magistrates by the Department of Defence for the information of the medical profession. It furnishes generally the requirements of the department in the matter of the medical examination of recruits for the Active Citizen Force, and requests medic [illegible]
in their names and [illegible]
which recruits may [illegible]
For each examination a fee of 5*s* only may be claimed. The whole circular is regarded as somewhat unfortunately worded. In the first place, it is evident that a thorough physical examination of every recruit is expected. If the examination is to be as thorough as the certificate indicates, it will take time and care on the part of an examining practitioner, and any fee of less than half a guinea would be ridiculous. The circular states that "medical officers who wish to do so may claim five shillings for each certificate." As thus phrased it clearly places the onus of demanding even the fee of 5*s* upon the practitioner. If he wishes to do so he may claim the fee, the inference being that the Government hopes but hardly expects, the practitioner to be patriotic enough to do the work for nothing at all. The real inducement, however, to the profession to volunteer appears in another clause of the circular, which reads as follows:—

> Later on the Government will have occasion to invite medical [illegible] ll to undertake [illegible] line of war, in [illegible] Incidentally [illegible] stributing the [illegible] actitioners are [illegible] ill be given to [illegible] force medical officers.

This is very objectionable, and at the least can only excite suspicion in the minds of practitioners that all is not as it should be. It is understood that the Government does not intend to organise any medical corps in connexion with the defence forces of the Union, at any rate within the next year, but expects to be able to muddle along with the aid of private practitioners. Thus the existing volunteer medical units will disappear and are not to be incorporated in the new defence force, as is the case with combatant corps. This seems to be regrettable, for new medical corps will not be easy *to create, while the experience gained in South African wars* has shown the necessity of an efficient organisation being created in advance. It is to be hoped that the existing volunteer corps may yet be saved.

Jan 7th

LONDON HOSPITAL MEDICAL COLLEGE.—The second of two lectures in clinical surgery will be delivered by Sir Frederic Eve on Tuesday, March 11th, at 1 P.M., in the clinical theatre of the hospital. The subject is Malignant Tumours of the Long Bones: their Pathology, Symptoms, and Treatment. The attendance of members of the medical profession is invited.

Obituary.

PHILIP HAIR, M.D. EDIN.,

PHYSICIAN TO THE CARLISLE DISPENSARY.

Dr. Philip Hair, the oldest medical practitioner in Carlisle, died somewhat suddenly last month, in his seventy-second year of age. He was the second son of James Hair, of Carlisle, and he received his medical education at Edinburgh, where he graduated M.B. and C.M. in 1866, obtaining the M.D. degree two years later, and being awarded the gold medal for his thesis on the Muscular Fibres of the Alligator. This thesis was published in the *Journal of Anatomy and Physiology*. For a time he was assistant demonstrator of anatomy in the University to Professor Goodsir and Professor (now Sir) William Turner, subsequently going to Paris, where he added to his professional knowledge and acquired great fluency in the French language. In this connexion it is of interest that when a decade or so ago Dr. Blanc and Dr. Forrestier of Aix-les-Bains visited Carlisle as the guests of the late Dr. Ware, Bishop of Barrow-in-Furness, and attended a meeting of the local medical profession, Dr. Hair returned thanks to the visitors in an eloquent speech in their own tongue. After his return from Paris Dr. Hair was elected surgeon to the Carlisle Dispensary in 1873, and later in 1898 became one of the physicians, a position which he held at the time of his death. In this institution he took a keen and active interest for more than 40 years.

Dr. Hair played a prominent part in two leading law cases. Some years ago he brought an action against the corporation of Carlisle with regard to the drainage of his house, the case being taken to the Court of Appeal and decided in his favour, and Hair *v.* Hill was for many years a precedent in such cases, though the decision was later upset by another similar case. An action which he brought against the North-Eastern Railway Company resulted in defining the meaning of the law as to the liability of railway companies for damage caused by sparks from engines. Dr. Hair leaves a widow and a daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Baudouin, formerly inspecting physician of the French Military Medical Service.—Dr. Manuel Araujo, President of the Republic of Salvador.—Dr. Giovanni Giudice, *agrégé* of the Turin Medical Faculty.—Dr. Rudolf Frank, *privat-docent* of surgery in the University of Vienna.—Dr. A. Isaac, formerly deputy for the Guadeloupe.—Dr. George F. Hanson, formerly professor of materia medica and therapeutics in Cooper Medical College, San Francisco.—Dr. Orville Horrwitz, formerly professor of genito-urinary diseases in Jefferson Medical College, Philadelphia.—Dr. James P. Tuttle, professor of diseases of the rectum in New York polyclinic medical school and hospital.—Dr. Henry Hervieux, professor of medical pathology in Laval University, Montreal.—Dr. W. J. van Stockum, senior medical officer of the Coolsingel Hospital, Holland.—Dr. Martin Gastesi, of the Dámaso Larrañaga Hospital, Montevideo.—Dr. Jacino Sicardi, a distinguished ophthalmologist and chief of the eye clinic of the San Roque Hospital, Buenos Aires. He had been assistant to Professor Reymond in Turin.—Dr. Ernest Palmer, professor of clinical gynæcology in Long Island College Hospital, Brooklyn.—Dr. Robert Murray, formerly director-general of the United States Military Medical Service.—Dr. Dhourdin, formerly professor of anatomy in Amiens.—Dr. Clavel, formerly inspecting medical officer of the French colonial troops.—Dr. L. Lantschner, formerly *privat-docent* of surgery in the University of Innsbruck.—Dr. J. Menno Huizinga, medical officer of health, Amsterdam, aged 63.—Dr. Arnold L. G. Heller, professor of general pathology and pathological anatomy in the University of Kiel. He had been a pupil of Rokitansky in Vienna, and afterwards lectured on pathology in Erlangen, whence he was invited to Kiel in 1872, and held the chair there until his death. He published researches on the parasites of the liver and intestines, on the cause of tuberculosis, and many other pathological questions.—Dr. H. Litzmann, Medical Privy Councillor, of Altona.—Dr. F. W. Benicke, Medical Privy Councillor, of Berlin.

THE NATIONAL INSURANCE ACT.

THE WORKING OF THE ACT.

THE time that has elapsed since the coming into force of the National Insurance Act does not allow of many definite statements to be made about its working in general and throughout the country, although many indications are fairly clear. But it is certain that one set of circumstances may press hardly in one locality and have little significance in another, while the character of the work and the *personnel* of the patients (to mention two very obvious things) will differ in different parts of the country and thus will affect the administration of medical benefit. We begin this week a series of articles by one of our staff, who has begun a course of personal investigation into the conditions under which medical benefit is being provided. When the time comes in which we have to press for amendments it will be of great value to have first-hand evidence upon which to act.

ADMINISTRATION OF SANATORIUM BENEFIT.

THE following is the text of the Memorandum on the *Administration of Sanatorium Benefit*,[1] *signed by* Mr. C. F. G. Masterman, and presented to both Houses of Parliament.

1. "Sanatorium benefit" consists of treatment given at the cost of the National Health Insurance Fund to persons suffering from tuberculosis or such other diseases as the Local Government Board, with the approval of the Treasury, may appoint. For the time being the benefit is confined to the treatment of tuberculosis.

2. The first duty of an Insurance Committee with respect to sanatorium benefit is to make provision for the treatment of cases of tuberculosis occurring among insured persons, for the administration of whose benefit they are responsible. They may, if they think fit, extend treatment to the dependents of insured persons or to any class of such dependents.

3. Treatment for purposes of sanatorium benefit may be given: (*a*) In sanatoria, hospitals, or other residential institutions; (*b*) at tuberculosis dispensaries or other non-residential institutions; (*c*) in the patient's home.

4. In administering the benefit Insurance Committees are not empowered by the Act themselves to provide institutions. Their duty is to make arrangements with suitable persons or local authorities for this purpose. All such arrangements are required by the Act to be made to the satisfaction of the Commissioners. In the case of those who require treatment in institutions the arrangements must be made with persons or local authorities (other than Poor-law authorities) having the [illegible] other institutions approved by the [illegible] treatment is required otherwise [illegible] must be made for it to be given by persons or local authorities (other than Poor-law authorities) undertaking such treatment in a manner approved by the Local Government Board.

5. Recognising that, notwithstanding what had already been effected by local authorities and voluntary effort, the available means of organised expert treatment in the form of sanatoria, hospital accommodation or dispensaries was far short of the needs of the population, Parliament provided under the Finance Act, 1911, a capital sum of £1,500,000 for the United Kingdom to aid the provision of institutions for the purpose. Having regard to the capital sum thus provided and in view of the early operation of the Insurance Act, it became advisable to consider the whole question of tuberculosis in all its bearings, and the Government accordingly appointed, in February, 1912, a Departmental Committee "to report at an early date upon the considerations of general policy in respect of the problem of tuberculosis in the United Kingdom, in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoria or other institutions or otherwise."

6. In view of the fact that the provisions of the Insurance Act relating to sanatorium benefit came into operation on July 15th, 1912, the Committee issued in April an interim report in which they laid down, for the assistance of all concerned in the administration of measures dealing with tuberculosis, whether among the insured or non-insured sections of the population, the broad lines of the scheme which they recommended for adoption in every area, and the recommendations of the Committee were concurred in, generally, by the Local Government Board and the Insurance Commissioners.

7. [illegible] Committee recognised that the provision for [illegible] when occurring among insured persons could [illegible]sidered as a separate problem. They made it their object "to take into consideration the existing machinery and funds available, and to indicate the lines upon which, in their view, a national and comprehensive scheme for co[illegible] in all its forms may be established and developed [illegible] to devise a scheme in which may be united [illegible] of the various bodies, authorities, and persons concerned, so as to ensure that adequate provision for the prevention and treatment of the disease should be made available on a systematic basis, as far as possible uniform in character, but not necessarily identical in detail, throughout the United Kingdom."

8. For the proper development of satisfactory schemes of administration in each area on the lines laid down in the report of the Departmental Committee, time was required in order that Insurance [illegible] County Borough Councils, and the other [illegible] concerned might consider the matter and [illegible]s also required, obviously, for the *erection*

Figures are appended to the Memorandum illustrating the operation of sanatorium benefit for the first four months up to Nov. 20th, 1912. In this period 3773 persons received sanatorium benefit. Of this number 2172 were treated in residential institutions, 587 at dispensaries, and 1014 at home under the care of private practitioners, the total cost being £37,640. Later figures, obtained since Nov. 20th, bring the total number of insured persons and their dependents who have received under the Insurance Act treatment in residential institutions in the period ending Feb. 4th, 1913, up to 4753.

A COMMITTEE ON DRUGS.

A committee has been appointed, consisting of Mr. J. Smith Whitaker (chairman), Mr. Walter Davies, Mr. J. C. Ledlie, Mr. Claud Schuster, and Dr. Lauriston E. Shaw, to inquire and report whether, having regard to the interests of insured persons in obtaining an efficient and rapid supply of drugs, medicines, and appliances, and to the conditions under which those articles were supplied before the passing of the National Insurance Act, 1911, any alteration is necessary in the conditions laid down by Section 15 (5) (iii.) of the National Insurance Act in respect of the matter. All communications in regard to the Committee should be addressed to the secretary, Mr. James Rae, at the National Health Insurance Commission (England), Buckingham-gate, London, S.W.

MIDDLESEX INSURANCE COMMITTEE.

AT its monthly meeting on March 3rd the Middlesex Insurance Committee decided to approve of a basis of payment to medical men on the panel. The following scale of charges was approved:—

	s.	d.
1. Attendance on patients at practitioners' residence or surgery...	1	0
2. Visit to patient's residence	2	0
3. Special visit	2	6
4. Night visit	2	6
5. Surgical operations	10	6
6. Administration of general anæsthetic...	10	6
7. Setting of fracture	10	6
8. Dislocation	10	6

It was explained that these figures were units, on the basis of which payments to medical men from a pool would be computed.

Some members expressed the opinion that the charge for night visits was not sufficient, and in reply the chairman of the committee, Mr. W. S. Glyn Jones, M.P., said that the scale was one suggested by the Ealing Division of the British Medical Association for a public medical service.

Mr. E. W. Lowry, of Brentford, moved a resolution in favour of adopting a wider interpretation of Clause 15 (3) of the Act, as to insured persons making their own arrangements, urging that a wide use of contracting out would be of great advantage to the Committee, the medical profession, and the insured. The motion, however, was lost by a large majority, only five voting in favour.

A BUSINESS INSURANCE AGAINST SICKNESS.

THE very marrow of the dissension that has been aroused between the medical profession as a whole and the Government over the question of the Insurance Act lies in the interference of the Act with the freedom of the relations between doctor and patient. The profession, for the most part, claims that the relation of doctor and patient should be individualistic if the best interests of the patient, of the public, of the doctor, and of medical science are to be conserved, and that any attempt to control those relations, must inevitably impair their effectiveness. The Government, on the other hand, insists that it would be impossible to organise any insurance scheme for the provision of medical attendance on the masses without some measure of control over the medical men employed, and over their relations with their prospective patients, and it supports its position by reference to the necessity for public control when the expenditure of public money is involved.

We have recently received from a Manchester insurance company a copy of its family medical policy for insuring families against liability for the cost of medical attendance, medicine, and surgical operations, which presents a scheme that, had it been adopted by the Government for the Act, might have in many respects obviated this troublesome clash of interests. Briefly the scheme is this. For each member of the family for whom a policy is taken out the sum of 2*d*. a week, or 7*s*. 6*d*. per annum in advance, secures the payment of all bills for medical attendance during the twelvemonth, including the cost of medicines supplied, whether by medical man or chemist, and surgical operations not exceeding 5 guineas, up to a total cost of £25, the first four visits of the year to each insured person being excluded. The fee allowed for each visit is 2*s*. 6*d*., or 200 visits in all. Double fees for night visits between 9 P.M. and 9 A.M. are allowed, and provision is made for higher fees in the event of the insured being medically attended while temporarily absent from home. Under this plan any medical man in whom the insured has confidence may be called in, subject to the limitation that the fees paid to him shall not exceed the rate of 2*s*. 6*d*.

per visit, exclusive of medicine supplied. It might happen, however, that the family doctor's fee is more than 2*s.* 6*d.* a visit. In such a case either (1) the insured would himself be liable in the ordinary way for the difference between the stipulated fee of 2*s.* 6*d.* and that actually charged for each visit; or (2) a higher premium could be arranged to cover the liability at a higher fee per visit. When the medical attendance is complete the practitioner renders his detailed account in the ordinary way to the patient, who, after checking it—which he would naturally do, so that what is practically his deposit account of £25 with the insurance company created by his policy shall not be unduly depleted—sends it to the company. The company at once settles the account, either direct with the practitioner or by sending to the insured a crossed cheque drawn in the medical attendant's favour. The insured's medical expenditure is thus limited to the cost of the first four visits (viz., 10*s.*), and the medicines supplied therewith, in any one year, plus the small weekly or annual premium. He has really the doctor of his choice, and is not limited therein by any panel; he is subjected to no vexatious restrictions, but proceeds exactly as he has always done, calling in the doctor in the ordinary way when he wants him, falling back on any other doctor if his own be not available, and changing his doctor, as he does now, without let or hindrance when he pleases and without needing anyone's consent. The doctor, for his part, enters into no other arrangements beyond those of ordinary practice, but he obtains immediate settlement for his fees for all visits after the first four, for surgical operations (up to 5 guineas), and for medicines supplied. His bad debts are thus reduced, the capital value of his practice should be increased, there is absolutely no interference of any kind between him and his patients, no departure is made from his ordinary methods, and no control or regulation exercised by any external authority. He is a free worker, as hitherto, but with this advantage—that he can depend on his fees being promptly settled in the case of all those of his patients who are thus insured.

The Insurance Act being compulsory on all workers of a certain class—who, indeed, are on the whole the least liable in the family to sickness—this provision is primarily intended not for them, but for the unprotected members of their families, men, women, and children, between the ages of 1 and 50 years. But some of the compulsorily insured who, in order to retain the services of the medical man of their choice, if he does not happen to be on the panel, must consent to forego the benefit of their compulsory premiums and meet out of their own resources the fees of their chosen medical attendant, may be glad to avail themselves of this opportunity of lessening their burden. This new departure in insurance, we are told, has been most cordially received by a large number of medical men in industrial districts, especially in the North of England.

The Insurance Committee for the County of London has removed from 3, Pall Mall East, London, S.W., to 5, Chancery-lane, London, W.C.

THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (HAMPSTEAD AND NORTHWOOD).—The annual court of governors of this charity, the anxious position of which was described in THE LANCET last week, will be held at 7, Fitzroy-square, London, W., on Wednesday next, March 12th, at 4 P.M., Lord Zetland, the president, in the chair. The committee will present a report of its proceedings and of all receipts and disbursements relating to the hospital during the past year and of the general state of the hospital. The following motion will be submitted for the approval of the governors:—

> That the committee of management of this institution be instructed to submit the hospital, situated at Hampstead, for sale by public auction or otherwise, and to take such steps as counsel may advise for vesting such hospital in the purchaser.

Dr. F. W. Tunnicliffe, chairman of the medical board, will bring forward the following amendment:—

> Considering that the entire medical and surgical staff has expressed the considered opinion that on medical grounds it is not practicable to conduct a chest hospital in the true sense of the term at Northwood, this meeting directs that the further consideration of the chairman's resolution be deferred until March, 1914, and that the committee of management be called upon to exercise, if necessary, the powers conferred upon them at the last meeting of governors to separate the two institutions with the view to "a further and better perpetuation of the hospitals at Hampstead and Northwood."

Medical News.

UNIVERSITY OF CAMBRIDGE.—The degree of M.D. has been conferred upon Mr. W. R. Honeyburne, Peterhouse.

UNIVERSITY OF OXFORD.—Mr. P. E. H. Adams, B.M., F.R.C.S. Eng., has been elected to the Margaret Ogilvie Readership in Ophthalmology.

UNIVERSITY OF SHEFFIELD.—The Council at its last meeting appointed Miss Sophia M. V. Witts, M.D. Lond., to the newly instituted post of lady tutor in anatomy

UNIVERSITY OF LONDON: KING'S COLLEGE.—The following appointments have been made in the Department of Public Health:—Dr. E. W. Routley, medical officer of health, Aldershot, as lecturer in sanitary law and administration; Colonel W. G. King, C.I.E., M.D., late Sanitary Commissioner in the Madras Presidency, as lecturer in applied hygiene in the tropics; and Dr. W. F. Roach, as lecturer on school hygiene for medical officers. The laboratories of the College occupy part of the premises of the Charing Cross Hospital Medical School, 62, Chandos-street, W.C.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. R. Cassirer, *privat-docent* of neurology, has been granted the title of Professor.—*Cagliari:* Dr. Carlo Ceni, extraordinary professor of neurology and psychiatry, has been promoted to Ordinary Professor.—*Catania:* Dr. Pietro Stancanelli, of Naples, has been recognised as *privat-docent* of Dermatology and Syphiligraphy.—*Florence:* Dr. Giuseppe Pasetti has been recognised as *privat-docent* of Ophthalmology.—*Padua:* Dr. Mario Fontana, of Rome, has been recognised as *privat-docent* of Physio-therapeutics.—*Palermo:* Dr. Erasmo Scimeni, of Messina, has been appointed Professor of Clinical Ophthalmology.—*Philadelphia Medico-Chirurgical College:* Dr. John J. Gilbride has been appointed Lecturer on Anatomy.

CENSUS OF HOMELESS PERSONS IN LONDON.—The census of homeless persons, taken every year in London on a night in February, showed this year a total of 649, a figure less by 554 than the total for 1912, and the lowest recorded number. This was accompanied by a fall of 973 in the number of inmates of common lodging-houses. The Public Health Committee, reporting to the London County Council on the matter on March 4th, expressed the opinion that this remarkable result pointed to the fact that, in addition to changes in the administration of the Poor-law, there were other unrecognised forces exercising a determining influence on these sections of the community. The committee noted that although the Metropolitan Casual Paupers Order, 1911, had brought about a considerable reduction in the number of persons resorting to casual wards in London, there had not been any increase in the number of vagrants in casual wards in areas adjoining the County of London.

ROYAL SUSSEX COUNTY HOSPITAL.—The effect of the Insurance Act was commented upon at the annual meeting on Feb. 26th of the Royal Sussex County Hospital at Brighton. It was stated that the weekly average of out-patients and casualties since Jan. 15th, 1913 (the date of the operation of the Insurance Act), had dropped by about one-third, but the number of in-patients was at exactly the same figure as in the corresponding weeks of last year. There was still misconception of what the medical benefits of the Insurance Act would do, but, said Mr. C. Scrase Dickins, the President, in the midlands and in the north employers of labour were recognising that it would not do to cease their contributions to voluntary hospitals. On the subject of the Insurance Act the following note from the annual report is to the point: "In spite of the adverse circumstances, the amount received in subscriptions is more than in 1911. The feared extinction of the voluntary hospitals is not come yet, and there is no indication that the people of Sussex desire to see anything of the kind take place. It is to be hoped that both employers and employed begin to realise more fully that, except in the case of tuberculosis, the Insurance Act provides no substitute for hospital in-patient treatment, and that the classes which needed it before will continue to need it now *Time will show whether there will be a sufficient* reduction in the number of out-patients to make possible any alteration in the existing arrangements It was never expected that the call on the beds would diminish, and the experience of last year does not indicate that it is likely to do so " The total number of in-patients during the year was 2709, as compared with 2690 in 1911, and out-patients 10,568, as against 10,340

CENTRAL MIDWIVES BOARD —A special meeting of the Central Midwives Board was held on Feb 27th at Caxton House, Westminster, Sir Francis H Champneys being in the chair The Board considered the following charges, *amongst others, against the midwives whose names are given* below, and ordered them to be struck off the roll —Mary Ann Harman, that being in attendance as a midwife at a confinement, the placenta and membranes not having been completely expelled two hours after the birth of the child, she did not hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E 20 (3), and she failed to take the pulse or temperature of the patient, as required by Rule E 13 Catherine Hickman, that being in attendance as a midwife at a confinement, the child suffering from inflammation of, *and discharge from, the eyes, she did not explain that the* case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E 20 (5) Clara Jane Lander, that she was not scrupulously clean, as required by Rule E 1, that she did not take with her to a confinement, nor did she possess, the appliances and antiseptics required by Rule E 2, and that she did not keep a register of cases, as required by Rule E 23 Louisa Lower, that being in attendance as a midwife at a *confinement she did not provide for the comfort or* cleanliness of the patient, as required by Rule E 11, and she falsely stated to the registered medical practitioner in attendance that she had washed the patient when in fact she had not done so Ruth Skelton, that she persistently neglected to comply with the rules of the Central Midwives Board, and that she did not keep her register of cases as required by Rule E 23 Florence Ann Smith, that she was guilty of misconduct in that she fraudulently and with intent to deceive made use of a fictitious document purporting to be the copy of a testimonial signed by the matron of the Monmouthshire Training Centre favourable to her application for appointment to the staff of King Edward VII *Hospital, Windsor, well knowing the same to be false, and* with intent to induce the members of the committee of such hospital to bestow upon her the said appointment Amy Stacey, that being in attendance as a midwife at a confinement she did not adopt the antiseptic precautions required by Rules E 3 and 7, she neglected to take the temperature of the patient at any time being unable to make use of a clinical thermometer and the case being one of stillbirth, and no registered medical practitioner being in attendance, she failed to notify the local supervising authority as required by Rule E 21 (1) Christina Helen Sutherland that being in attendance as a midwife at a confinement the child suffering from discharge from the eyes, she did not explain that the case was one in which the attendance of a registered medical practitioner was required nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner as required by Rule E 20 (5) and that she treated the child s eyes with chloride of mercury and silver nitrate but made no entry of their administration in her register of cases as required by Rule E 18 Sarah Ann Ward that being in attendance as a midwife at a confinement she did not wear a clean dress of washable material, as required by Rule E 1, she did not wash *or scrub her own hands or forearms before touching the* patient s generative organs, as required by Rule E 3, and she did not wash or swab the patient prior to making the first internal examination, as required by Rule E 7 The following midwives were censured after charges against them had been considered Sarah Harris and Flora Wright

DR Louis Vintras, physician to the French Hospital in London, has been made a Knight Grand Cross of the Order of the Knights Hospitallers of St John in Spain

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC —The annual general meeting of this institution will be held at 22 Chenies street, London, W C, on Friday, March 14th, at 5 15 P M, when the chair will be taken by Sir W J Collins, F R C S

THE HUNTERIAN SOCIETY —The annual medal has been awarded to Dr A Graham Stewart for an essay on "Raised Arterial Pressure and Arterio sclerosis" Dr Graham Stewart will read a paper, founded upon the essay, at the annual meeting of the society on April 23rd

HEALTH OF PAIGNTON (DEVON) UNVACCINATED CHILDREN —The medical officer of health of Paignton in his annual report for 1912 states that the death rate was 13 4 per 1000 and the birth rate 16 7 per 1000 He urges the importance of erecting, in accordance with Local Government Board requirements, a special block of buildings for the isolation of small pox cases, as 70 per cent of the children born in Paignton are unvaccinated

DAWLISH (DEVON) COTTAGE HOSPITAL —At the annual meeting of the subscribers to the Dawlish Cottage Hospital, the medical report and the financial statement were satisfactory Mrs Nosworthy has recently completely refurnished the hospital at a cost of £200, and the late Mr E Bayldon bequeathed £100 for its heating apparatus It was unanimously decided that insured persons with no dependents shall be received as in-patients only on payment of three fourths of their sickness benefit

SAMARITAN FREE HOSPITAL FOR WOMEN —The annual general meeting of governors will be held in the board room of this hospital in Marylebone road, London, N W, on Tuesday next, March 11th, at 5 P M, when among *the business to be transacted will be the following* amendment of Rule XII, proposed by Dr F J McCann and seconded by Mr G F Darwall Smith —

That Rule XII shall read —
consist of (1) the governors elect
(2) the following *ex officio* memb
two members of the active staff
mittee and not more than fo
Three members shall form a quorum

TUBERCULOSIS TREATMENT IN MIDDLESEX —The Local Government Board has signified its approval of a scheme prepared by the Middlesex county council for the treatment of tuberculosis The public health committee reported to the council on Feb 27th that the sum available for general tuberculosis treatment having been reduced in consequence of the decision of the Government to earmark 6*d* per insured person in respect of remuneration to general practitioners for domiciliary treatment, only 350 instead of 450 beds could be provided in hospitals and sanatoriums The council should let it be clearly understood that no further beds would be provided until an increased grant from the Exchequer was assured The council approved this report and authorised the public health committee to appoint five tuberculosis officers at a salary of £500 a year each, and two assistant tuberculosis officers at £300 a year each, and to make arrangements for obtaining premises in various parts of the county suitable for dispensaries

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN BRITISH GUIANA.

The health of this colony during the year, April, 1911, to March, 1912, was fairly satisfactory, there having been no outbreaks of plague, yellow fever, or small-pox, and the death-rate having been 31·7 per 1000, compared with 34·4 per 1000 in the previous year. The birth-rate was 27·5 per 1000. Malarial fevers are prevalent, but great improvement has been effected in recent years. In 1906–07 the cases treated in the estates hospitals numbered 33,748; in 1910–11 they were 21,063; in 1911–12 they had fallen to 15,169. This diminution has been due to the adoption of vigorous anti-malarial measures, the chief of which have been the abolition of mosquito breeding grounds and free distribution of quinine. Ankylostomiasis has been extremely prevalent on the sugar estates in the colony, and the introduction every year of a large number of infected East Indian immigrants renders the eradication of the disease a matter of great difficulty. The measures adopted are: (1) erection of latrines; (2) systematic examination of all newly arrived immigrants and of all persons suffering from anæmia or showing the least signs of being infected with the parasite; and (3) treatment and constant observation of all known infected cases. Dr. J. E. A. Ferguson, of the Peter's Hall medical district, states that in 1904 the great majority of the coolies harboured the parasite, their efficacy for work being very much impaired, women being rendered sterile by the accompanying anæmia, and deaths being frequent; by the use of 10 grains of thymol, either in a cachet or preferably coated with chocolate in a "pulverette," given nightly except on Saturdays, the ova gradually diminish in the dejecta, and after four months entirely disapper; no ill-effects whatever are produced. The same medical officer has been successful in combating malaria by the regular administration of quite small doses of quinine. A spleen census is taken, and to the coolies with normal spleens a weekly dose of 5 grains is given; to those with the spleen enlarged a similar dose is given daily, with an additional 5 grains if the enlargement is very great. This very simple treatment is said to have caused marked reduction in malaria, both in attacks and deaths. The birth- and death-rates on the Diamond Estates had averaged 29·7 and 24·7 per 1000 respectively for the years 1908–11; since the adoption of this treatment at Providence these ratios have been (1911–12) 35·3 and 16·9 respectively. The bacteriological department reports unfavourably on the use of nastin in the treatment of leprosy, but states that benzoyl chloride in petroleum oil is extremely valuable as a nasal spray or paint for ulcerating surfaces; it quickly renders the discharge free from bacilli. The report of the Surgeon-General, Dr. J. E. Godfrey, with accompanying subsidiary reports, states the present condition of medical matters in British Guiana; but as no ratios of disease prevalence or mortality are mentioned, and but few references made to previous statistical reports, it is not possible to compare the condition of this colony as regards its public health either with that of other colonies or with its own record in previous years or decennial periods. The interest and value of the report are therefore, we think, considerably diminished.

OLD AGE AND RECUPERATIVE POWER.

To the Editor of The Lancet.

Sir,—I think I can match Dr. W. Vernon Shaw's case published in The Lancet of Feb. 8th, p. 431. Some few years ago during one of the influenza epidemics I was called to see an old lady nearer 100 than 90. Her complaint took the form of bronchitis, and instead of trained nurses we had the kindly ministrations of her two daughters, middle-aged ladies. She said that she hated doctors and medicine. She read her daily paper and was very active mentally and otherwise. At the time I happened to have an accumulation of sample bottles of a medicinal wine. This was the only physic given. She was comatose for two whole days, her mouth was full of "thrush," and we were naturally waiting for the end. But she persisted in recovering. They eventually went to live at Ventnor, and a notice of her death, aged 102, appeared in The Lancet. Nowadays our old friend "Vis medicatrix Naturæ," I am afraid, is not so much trusted and relied upon as formerly.

I am, Sir, yours faithfully,

Crouch End, March 2nd, 1913. F. Orton, M.D. Dub.

THE ARMY AND NAVY MALE NURSES' COÖPERATION.

The fifth annual report of this association has been issued. The object of the association is to organise and utilise in civil employment the fully qualified male nurses who have received a costly training in the army and navy which is likely to be wasted on their leaving the service, since they often drift into unsuitable employment where their skilled training finds no market value. By their employment in civil life a double public need is subserved, for not only are these deserving men found employment in which their skilled training renders them of special value, at the same time providing for a constant public need, but their efficiency as reservists, who will be called out to serve their country again in the event of war, is not allowed to deteriorate in time of peace The Coöperation, of which Queen Alexandra is patroness and the Duke of Connaught patron, the president being Admiral Sir John Durnford, K C B (vice Sir Frederick Treves recently retired) and the chairman Sir Dyce Duckworth, maintains a residential home for the nurses at 11A Welbeck street, Cavendish square, thus assuring to the public that the nurses come direct from suitable surroundings and giving facilities for a personal interview with the nurse before engaging him The terms are moderate—2 guineas a week, 10s 6d a day or night of 12 hours, or 5s 6d an hour Applications for nurses should be made to the Secretary, 11A, Welbeck street, London, W

A QUESTION IN LUNACY CERTIFICATION

To the Editor of THE LANCET

SIR —A has a club patient who has been a subscriber of his for 14 years During the last three months he has shown symptoms of insanity, which became so pronounced that on Saturday, Feb 22nd, the relations were told by A to go to the relieving officer and to make arrangements with a magistrate living in the place, and that he A, would meet them at the patient s home on the Monday at whatever time was arranged Hearing on Sunday the relieving officer was from home, no arrangement was made with A Nothing further was heard by A either on Monday or Tuesday, so on Wednesday he visited the patient, and to his surprise found that he had been taken to the asylum on the Monday On further inquiry it transpired that the magistrate (a miner, who was also from home on business) could not be present, so the chairman of the urban district council, an *ex officio* J P (also a miner), was asked by the relieving officer s son (acting in his father s absence), who (i e , the J P) in turn asked *his* medical attendant, B a stranger to the patient, to examine the case with him B (who lives quite close to A) did so It is hardly necessary to say anything about B s etiquette, but has a magistrate any right to ignore a patient s own medical man in such a case ? The poor wife (poor in a double sense) was greatly annoyed, but told me she did not like to say anything Both B and the magistrate knew that the patient was A s A has not spoken to B about it as yet, as he desires to know his position first

I am, Sir, yours faithfully,

March 3rd, 1913 B A , M D

*** The Lunacy Act says nothing about the one medical certificate which is required in urgency orders being signed by the medical man in regular attendance Of the two medical certificates required with reception orders on petition, one must, whenever practicable, be signed by the practitioner in regular attendance, and it seems clearly desirable that where an urgency order is necessary the one certificate accompanying it should be that of the usual medical attendant The chairman of the urban district council in the case described apparently knew in whose medical care the patient was and in our opinion he should have made an effort to secure his attendance in the *patient s interest and as a matter of courtesy*, but we do not see that B could do otherwise than conform with the instructions of the magistrate —ED L

SOUTH AFRICAN SNAKES

FAR too little is known by the average practitioner in South Africa on the subject of the snakes commonly met with in that country Mr F W Fitzsimons, the curator of the Port Elizabeth Museum has recently revised his book, ' The Snakes of South Africa, and the results are to be found in the second edition, which has been published in Cape Town The book is intended primarily for laymen but it contains much that will appeal to the practitioner The addenda particularly are noteworthy, including as they do memoranda on experiments carried out in the Government laboratories Mr Fitzsimons writes in an entertaining style, and apart from the value of the work from the standpoint of natural history, which is considerable, he has succeeded in producing a book that should be useful to the medical profession

A PAMPHLET FOR INSURED PATIENTS

MEDICAL men on the insurance panels more particularly those in rural districts, would find very useful for distribution among their insured patients a little pamphlet on the National Insurance Act by Mr C Clark Burman, L R C P & S Edin , of Alnwick, Northumberland which describes in the most temperate reasonable, and convincing manner the responsibilities rights duties and privileges of insured persons and medical men under the Act It explains very clearly why the exercise of certain consideration for the medical man s time and convenience is so necessary showing that far more than the doctor s comfort, his professional efficiency, and consequently the welfare of his patients collectively and individually, is dependent on the exercise of such consideration and forbearance No price is mentioned, but the paper is published by J C Grant, the *Guardian* Office, 21, Bindgate Within Alnwick

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY

SPECIAL MEETING OF FELLOWS OF THE SOCIETY: at 5 P M

Discussion

On Alimentary Toxæmia its Sources, Consequences, and Treatment

Opening Addresses

Dr Hale White General Survey

Dr F W Andrewes The Bacteriology of the Alimentary Canal

Dr Vaughan Harley The Toxins of the Alimentary Canal

Dr Robert Saundby Consequences and Treatment from a Medical Point of View

Mr Arbuthnot Lane: Consequences and Treatment from a Surgical Point of View

Mr J F Colyer Consequences and Treatment from a Dental Point of View

The discussion will be re-opened by Mr J B Lawford on Monday, April 14th at 5 P M , and will be continued on successive Mondays for as long as may be necessary

TUESDAY

SECTION OF PSYCHIATRY (Hon Secretaries—R H. Cole, Bernard Hart) at 4 30 P M

Clinical and Pathological Meeting at Claybury Asylum

Cases

D [illegible]

L [illegible]

D [illegible] Decompression

Demonstrations

Dr F W Mott, F R S (1) Some Recent Investigations on the Bio-chemistry of the Neuron, (2) Spirochæta Pallida (Noguchi) in Culture (living), (3) Changes in Central Nervous System in a Case of Myxœdema, (4) Changes in Central Nervous System in Two Cases of Pellagra

SECTION OF SURGERY (Hon Secretaries—James Berry, J. Murray) at 5 30 P M

[illegible] n as a [illegible] with [illegible]

Mr. J Hutchinson The Symptoms produced by Aberrant Renal Arteries and a Clinical Study of the Indications and Results of Operation

WEDNESDAY

SECTION OF OPHTHALMOLOGY and SECTION OF NEUROLOGY at 8 P M } Combined Meeting

Discussion

On Disease of the Pituitary Body will be re-opened by Dr H. G. Turney and Dr Grunbaum

Specimens will be shown by Dr Grunbaum Dr William Hill, and others

THURSDAY

SECTION OF DERMATOLOGY (Hon Secretaries—Wilfrid Fox, J M H MacLeod) at 5 P M

Cases

Dr [illegible]

The Arris and Gale Lectures

ON

THE GENITAL FUNCTIONS OF THE DUCTLESS GLANDS IN THE FEMALE.

Delivered at the Royal College of Surgeons of England on March 10th and 12th, 1913,

By W. BLAIR BELL, B.S., M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond.,

GYNÆCOLOGICAL SURGEON TO OUT-PATIENTS, ROYAL INFIRMARY, LIVERPOOL; EXAMINER IN GYNÆCOLOGY AND OBSTETRICS TO THE ROYAL COLLEGES OF SURGEONS AND PHYSICIANS, LONDON; AND TO THE UNIVERSITY OF DURHAM.

LECTURE II.[1]

Delivered on March 12th.

Mr. President, Ladies, and Gentlemen,—In the last lecture I endeavoured to estimate the direct and indirect influences of the ovaries in regard to the genital functions. In considering the indirect influences I discussed the effects of ovarian insufficiency, both in physiological and pathological circumstances, on what I may perhaps describe as the rest of the genital system of ductless glands, and I also demonstrated the effects produced on the general metabolism by this condition. In this lecture I shall reverse the process, and endeavour to trace as far as possible in the time at my disposal the influence of the rest of the ductless glands upon [illegible]

[illegible] phile system may be considered similar in function to the medulla of the suprarenals, since their method of development and physiological properties are the same. We know too little of the coccygeal body to discuss it. The most recent investigators attach no importance to this structure as an organ of internal secretion. Nor shall I consider the internal secretion of the pancreas, for concerning this also we have no evidence of value in regard to the subject we have in hand. It is probable that every cell in the body is a ductless gland, and has some influence on the life and functions of the rest. But at present such a conception exists only as a dream in the minds of philosophical biochemists.

The two great generalised functions of all living tissues are: firstly, the coördinated development and life of the individual; and secondly, the reproduction of the next generation.

The aggregations of the specialised cells for the regulation of the body metabolism, which are known as the ductless glands, have long been identified as having an important bearing on the well-being of the individual—that is, on the growth of the body, on the coördination of his or her structures, and possibly on the maintenance of health by the production of antitoxic bodies. But it is only of recent years that these same groups of cells have been shown to possess most important special influences over that other great function of the living organism—the reproduction of the species in all its intricate necessities. Even now we have only hazy notions as to what these influences are, so that every fact and every observation, positive or negative, right or wrong, should be carefully recorded, in order that little by little the missing links in the chain of physiological interaction that connects all these organs together may be fitted into place.

The Relation of the Thyroid to the Genital System.

We shall, perhaps, be in a better position to consider the changes that occur in the rest of the genital system if we first discuss the effect on the general metabolism of removal of this organ.

Effects of Thyroidectomy on the General Metabolism.

Different mammals vary very much in their power of withstanding the disastrous results which may follow complete removal. I have never observed any grave effects supervene on the removal of the thyroid in rabbits. This has been explained on the ground that the parathyroids are relatively large, and lie well away from the thyroid itself, and consequently cannot be removed without a careful search; in other words, they escape removal during the operation of thyroidectomy. Swale Vincent and Jolly have shown that after thyroidectomy the parathyroids actually secrete colloid, and, in fact, perform the functions of the thyroid, just as they resemble it in structure, after this operation. But I do not believe that this question of the remaining parathyroids is the whole truth.

I think rodents have less need of the thyroid than other mammals such as the carnivora. It may be because the diet is different, but also I feel sure it is due in some measure to the variations in the structure and function (or degrees of function) seen in the other ductless glands. I have already alluded to the differences in structure between the ovaries of rodents and the higher mammals.

If, however, we take cats and remove their thyroids many die in a few days, usually with convulsions. In these cases it is probable that the immediate result is due to the removal of the whole thyroid apparatus (thyro-parathyroid). Some, however, survive the operation for a long period of time. In all these cases one can demonstrate the removal of the whole thyroid together with the internal parathyroids which are embedded in the two lobes of the thyroid. So that one gets in these animals the true effects of thyroid insufficiency. The number in which the metabolism was investigated fully was small, for, as already stated, many died too soon for the metabolism, as represented by the urinary excretion, to be estimated. The record of one non-pregnant cat which was destroyed two and a half months after operation has been selected as typical. (Table III., cat No. 9.) Other cases were complicated by the cats having had kittens shortly before operation, and in consequence did not appear to be suitable for averaging.

It will be seen that in this animal acetone was present three times in 20 estimations after operation.

The calcium excreted after operation was the same in quantity as before operation. There is a drop in the phosphorus excretion, in spite of the increase in the post-operation specific gravity; and the total nitrogen and urea are increased out of proportion to this rise in the specific gravity. It will be noticed, also, that the ammonia coefficient is slightly increased.

I am well aware from my experience in these matters that the records of one animal cannot carry much weight. But this was my only uncomplicated and reliable result out [illegible] l. [illegible] on the rest [illegible] rather important series of experiments in which thyroidectomy was performed on three pregnant cats which survived the operation for some time. They were carried out in order to observe the influence of the thyroid on the metabolism during pregnancy, especially with reference to the possible production of the symptoms of eclampsia with marked alterations in the ammonia coefficient. Further, I had in my mind the possibility that the secretion of the fœtal thyroids might reach the mother's circulation and mitigate the effects of the thyroidectomy performed on her.

The records of each case (Table IV., cats Nos. 2, 6, and 10) are drawn up to show the metabolism before operation, and in two cases after operation and before parturition. In one case the kittens were born alive at full term two days after the operation, before the estimations of the urinary metabolism had been resumed. It may be pointed out here that no estimations were carried out for a few days after any operation in order to avoid the effects of the anæsthetic.

It will be noticed that acetone, albumin, and sugar were found a good many times after operation in cat No. 2, and more frequently after parturition than before, without any real disturbance of the ammonia coefficient. Cat No. 10 gave birth ten days prematurely to stillborn kittens.

Turning to the averages (Table V.) we see that so long as the cats remained pregnant the calcium excretion remained constant, but that after parturition it was increased to treble the quantity. The phosphates after the birth of kittens showed a remarkable increase; and there is a considerable decrease in the urea excreted. There was, however, no disturbance of the ammonia coefficient.

---

[1] Lecture I. was published in The Lancet of March 22nd, 1913, p. 809.

It does not appear probable, therefore, that the thyroid is in any way specifically connected with the production of eclampsia, as was originally suggested by Nicholson. It is true that two of our cats (Nos. 4 and 5) not included in the series, which were in the first half of pregnancy, died with convulsions in a few days, but the manner of death was similar in every respect to that seen in non-pregnant animals in similar circumstances.

The evidence of my experiments is in favour of the possibility that in the latter half of pregnancy the secretion of the fœtal thyroid may be conveyed to the mother.

We now come to the consideration of thyroidectomy on the rest of the genital system.

Effect of Thyroidectomy on the Ovaries and Uterus.

The normal ovary of the cat, with which animal we are concerned in these experiments, shows certain affinities for eosin in some of its elements. The zona pellucida, the liquor folliculi, the interstitial cells, and the cells of the corpora lutea all stain faintly with eosin. After thyroidectomy all these elements show an increased avidity for eosin. This is especially true of the zona pellucida and the liquor folliculi, and appears to be a matter of some importance.

It seems that removal of the thyroid calls for a response from the ovary, just as oöphorectomy did from the thyroid. And the nature of the response, if my observations be correct, is one of considerable interest, for it brings forward evidence that the granulosa cells of the Graafian follicle form an organ of internal secretion. But this secretion is not connected with the integrity of the uterus, for the effect of thyroidectomy on this organ is remarkable. The uterus atrophies to a considerable extent. Fig. 8 (which appeared in Lecture I., p. 815) represents the uterus of a normal cat, and Fig. 10 that of a cat after thyroidectomy. It will be observed that the uterus of the thyroidectomised cat shows very considerable muscular atrophy, quite as much as occurs after oöphorectomy. In this case the cat was pregnant when the thyroid was removed, the kittens were born two days later, and the animal died at the end of a month. The condition might, therefore, be described as one of superinvolution. But the same effect is obtained in the non-pregnant animal. The importance of this intense

atrophy will be considered directly; for before drawing our final conclusions of these results it will be advisable to consider the clinical observations that have been made in regard to insufficiency of the thyroid.

Clinical Observations on the Effect of Thyroid Insufficiency on the Genital Functions in Women.

These are quite well-known. We frequently see young girls with adiposity suffering from amenorrhœa; or we see the more marked insufficiency which produces myxodema, and is also invariably associated with suppression of the menstrual function.

Now both the minor and the major state of thyroid insufficiency are readily amenable to thyroid treatment, with one reservation—if the girl has suffered from thyroid insufficiency for some years past the period of puberty, and has never menstruated, then it may be impossible to relieve her genital condition, and the uterus may remain underdeveloped. If, on the other hand, the insufficiency has arisen later, after the subject has possessed full genital activity, then the uterus may, even after a long period of inactivity, resume its normal functions. I remember a lady who developed myxœdema and did not menstruate for some years. After a course of thyroid treatment she not only menstruated regularly but conceived.

Thus we have an explanation of the condition of the uterus sometimes observed in women with thyroid insufficiency. It is a condition of atropy such as is seen in wild animals during seasonal inactivity, and it is one which can be reawaked to full activity, like the physiologically inactive organ. Further, the full and increased activity—if my interpretation of the staining properties be correct—of the secretion of the membrana granulosa cells, with inactivity of the uterus, puts out of court the hypothesis that the cyclic changes in the uterus are due to this secretion. On the other hand, it is possible that the secretion of the interstitial cells is rendered insufficient in the absence of thyroid secretion. It is along these lines that I am endeavouring at the present time to solve the question of obtaining an active extract for therapeutic purposes in cases of ovarian insufficiency.

To complete the picture of thyroid insufficiency we must note the changes that appear constant in the suprarenals and pituitary in these circumstances. Later we shall have to consider these ductless glands more fully.

Effect of Thyroidectomy on the Suprarenals.

The normal suprarenal structure is well-known, but I shall refer to it briefly in order better to illustrate the changes that occur, physiologically and pathologically, in the cat. The suprarenal is divided into two parts, the cortex and the [illegible]

Abelous and his co-workers suggest that the cortex produces pro-adrenin; this is supported by Schäfer and Herring, and appears highly probable. In addition, the cortex has direct genital functions to be referred to later.

Now the changes that seem to indicate excessive activity of the suprarenals occur in the cortex; and they may be seen normally in pregnancy, and, so far as we know, in ordinary circumstances. The normal appearances differ, however, from those associated with the activity following thyroidectomy. In three of my animals an actual calcareous deposit was found in the zona fasciculata subsequently to thyroidectomy. I have not seen this condition in a normal suprarenal gland. I take it that what occurs is the production of fatty substances in quantities greater than can be immediately dealt with; then calcium soaps are formed, and finally calcareous deposits are produced, just as may occur elsewhere in the body after a similar series of chemical reactions. Evidently, then, thyroidectomy stimulates the suprarenal cortex to excessive secretion, and this no doubt tends to produce calcium retention and prevent excretion.

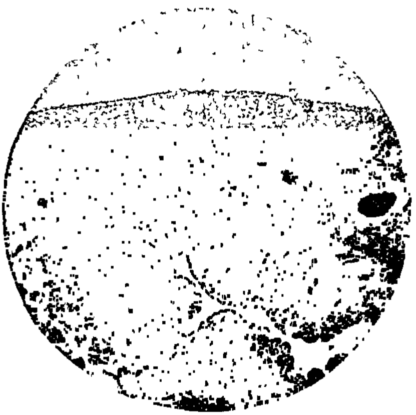
Effect of Thyroidectomy on the Pituitary.

That changes occur in the pituitary after thyroidectomy has long been known. Rogowitsch was the first to call attention to the fact. Herring states that the only change to be noted is an increase in the number of what he calls 'hyaline bodies' in the pars nervosa. These so-called 'hyaline bodies' are supposed to represent the secretion of the pars intermedia. But there can be no doubt that some—if not all—represent degenerated pars intermedia cells which have migrated into the pars nervosa. There the secretion, in my opinion, becomes converted into a pressor substance (infundibulin).

While it is, of course, quite certain, as Herring first observed and Cushing also noted, that this process does occur, I have found that it is not always so marked as we have been led to expect. Also in contradistinction to Herring, I have found definite changes in the anterior lobe. These were most marked in animals which were pregnant when thyroidectomy was performed.

The changes that occur seem to be an increase in active eosinophile cells at the expense of the large basophiles; and both in the pregnant and non-pregnant animal there is an increase of large active chromophobe cells, such as occurs normally in pregnancy. The latter are, of course, most pronounced in an animal in which thyroidectomy has been performed during pregnancy. The condition was well seen in cat No. 10 of my series. Ten days after operation two premature kittens were born. After a further interval of 120 days the animal was destroyed with chloroform. In this length of time all the chromophobe 'pregnancy' cells would have disappeared in the ordinary course of events. But as the result of thyroidectomy they not only persisted but showed an increase in secretory activity. The secretion appeared to form vacuoles among the cells. In this case the pars nervosa showed no abnormal invasion of pars intermedia cells. In the case of a non-pregnant cat (No. 9), killed 79 days after thyroidectomy, again many active chromophobe cells were to be seen in the pars anterior, and an increase in active eosinophile cells at the expense of the basophiles.

FIG. 10.



Uterus of cat one month after thyroidectomy. Atrophy of muscle coats. × 75.

We learn, then, from these observations that thyroidectomy causes an increase in the secretory activity of all parts of the pituitary body.

THE RELATION OF THE PINEAL TO THE GENITAL SYSTEM.

The pineal gland has never been successfully removed from mammals; and, owing to its inaccessible position in the brain, there seems to be little likelihood of experimental extirpation ever giving satisfactory results. The effects of castration on the pineal have already been mentioned.

The only other direct evidence available is that obtained clinically.

Clinical Effects of Pineal Disease on the Genital System.

Comparatively few observations have been made, but in most cases where a tumour has been observed it has been a teratoma, and somewhat remarkable symptoms have been seen. When the patient was a child, as was usually the case, there was a precocious development of the skeletal structures, and also of the genital organs. According to L. Kidd, who has recently reviewed the literature of the pineal body; all the cases recorded occurred in boys. In a few instances obesity has been seen, but apparently unaccompanied by genital atrophy.

Biedl thinks that the sexual precocity is due to insufficiency of the pineal body, and that the normal pineal secretion restrains the development of the genital organs. There is no reliable evidence in support of the latter statement.

The Relation of the Pituitary to the Genital System.

Some of the normal physiological changes in the pituitary which occur are well known. But there is much need for a systematic investigation into the age changes in this organ. So far as I know only a few isolated observations have been recorded.

There is reason to believe that the secretions of the pituitary determine many of the metabolic functions necessary for the establishment of puberty or sexual maturity.

We fully recognise the remarkable enlargement and the histological changes that occur in this gland as the result of pregnancy. The eosinophilia disappears and a large portion of the cells of the pars anterior become chromophobe, and, as already mentioned, have been called 'pregnancy cells.' No doubt this change is brought about by the needs of the maternal metabolism which the development of the fœtus entails. The changes seen in the pituitary during pregnancy cannot be produced to the same extent experimentally.

A few years ago Dale, and Hick and I, showed that an extract of the posterior lobe produces powerful uterine contractions. This effect may be produced physiologically in labour by the infundibular extract.

Ott and Scott first showed that the same extract is a galactagogue. It is not known how this result is produced; but most of the evidence goes to show that it is an expressor effect. It would be interesting if it were a fact, of which we have no proof, that the pituitary normally promotes the secretion of milk. It is, however, in my opinion certain that after the birth of the child the stream of metabolic products directed to its maintenance and growth in the womb are diverted to the mammary secretion, which is to supply its post-natal necessities.

I will now shortly recapitulate the work of others in regard to extirpation of the pituitary, partial or complete, in so far as it is of importance to our subject. At the same time it is necessary to state that none of the experimental work fulfils the highest ideals owing to the inaccessibility of this organ; consequently, the last word has not been said in regard to the results that may be obtained.

Effects of Removal of the Pituitary (Partial or Complete).

Most of the early work on the extirpation of the pituitary was absolutely unreliable, and it was not until Paulesco improved the technique, which Harvey Cushing and Biedl subsequently adopted, that results worthy of consideration were obtained.

Cushing's conclusions may be summed up as follows: Complete extirpation caused death in a short time. The same effect was obtained by complete extirpation of the pars anterior. Partial removal of the anterior lobe led to the condition known as dystrophia adiposo-genitalis—that is to say, there was great obesity, with atrophy of the genital organs and undergrowth in young animals.

Biedl confirmed these findings, and also stated that the posterior lobe (pars intermedia and pars nervosa) might be removed without producing symptoms.

It is difficult to believe in the results of experiments in which the anterior or posterior lobe are said to have been removed separately. But there can be no doubt that partial removal of the anterior lobe is not difficult to accomplish; and the results following this procedure should be reliable.

It is the effect of dystrophia adiposo-genitalis which is particularly interesting to our present study. And it is to be noted that Cushing in his recent work, if I understand him correctly, puts forward views diametrically opposed to the results obtained in the experiments which were previously published by him. He now attributes the symptoms mentioned to insufficiency of the posterior lobe. Thus the confusion that has so long existed becomes "confusion worse confounded," and, as already stated, can in my opinion only be dispelled by considering the whole pituitary as one organ.

Effects of Removal of the Pars Anterior on the Ovaries and Uterus.

There appears to be no doubt that the ovaries undergo hypoplasic changes after partial removal of the anterior lobe. There is no good description of the histological appearances, but Cushing states that the follicles disappear while the interstitial cells persist. The uterus also undergoes atrophy. I have had no opportunity of examining ovaries after this operation, but since the uterus atrophies one would have expected to find the same changes as those which follow thyroidectomy—that is to say, the reverse of what has been found by Cushing.

Effect of Removal of the Pars Anterior on the Thyroid.

It has been noted by Cushing and others that there is a remarkable degree of hyperplasia in the thyroid after partial removal of the anterior lobe. This condition is said to subside eventually, and be superseded by a considerable colloid formation, with apparent disappearance of epithelial activity.

Effect of Removal of the Pars Anterior on the Thymus.

This leads to hypertrophy of the thymus just as the condition of hypopituitarism is often associated with thymus enlargement.

Effect of Removal of the Pars Anterior on the Suprarenals.

The operation, according to Cushing, is followed by hyperplasia and lipoid vacuolation of the cells of the zona fasciculata.

Clinical Observations of the Effect of Pituitary Insufficiency on the Genital Functions in Women.

These have been made chiefly in regard to acromegaly and the condition already described as dystrophia adiposo-genitalis. The former disease is supposed to be due to excess of secretion and the latter to deficiency. The relationship of these two conditions, however, is not quite so simple as the above statement would seem to imply.

It is usual to find amenorrhœa both with acromegaly and with the condition which is supposed to represent the opposite, in regard to secretory activity.

With acromegaly the excessive thickening of bones indicates calcium retention—a condition which appears associated with masculinity, as we shall see when dealing with the suprarenals. Not long ago I saw with Dr. Amand Routh a patient with acromegaly who developed a deep voice, and had a very considerable hypertrophy of the clitoris. Some might be inclined to attribute this to suprarenal involvement in a polyglandular syndrome. According to Cushing, however, hyperpituitarism (acromegaly) is often associated with low blood pressure, asthenia, and pigmentation, which indicate suprarenal insufficiency, and not the reverse. Indeed, I have seen a case of acromegaly which presented all the symptoms of Addison's disease.

In view of these facts we must look upon acromegaly as a condition which produces masculinity and consequently amenorrhœa.

In cases of dystrophia adiposo-genitalis genital atrophy is invariable, yet there is no doubt that if the individual has had functional activity before the onset of the disease this activity may return on relief of the condition by decompression or by the administration of pituitary extract. I have myself observed this result follow injections of anterior lobe extract in dystrophia adiposo-genitalis. Similarly I have seen good results after the administration of this preparation in cases in which the patient was very obese and suffered from amenorrhœa, without showing the signs of intracranial pressure, which are usual when the condition has reached the stage of dystrophia adiposo-genitalis.

Success is the more likely when the patient has had some functional activity previously; but it is possible that delayed menstruation with obesity might be successfully treated if the patient has not long passed the usual age of puberty.

The Relation of the Thymus Gland to the Genital System.

The thymus has been shown to have a very important relation to the development of the individual and of her reproductive functions. It is probable that once the genital functions are established the thymus rapidly undergoes atrophy, and plays no further part in the metabolism of reproduction. We have already seen that the thymus undergoes hyperplasia after removal of the ovaries.

Effects of Thymectomy on the Ovaries and on the Calcium Metabolism

Paton found that if the operation be performed before puberty there is a rapid development of the genital gland It appears, therefore, as if the thymus either inhibits the development of the ovaries (Biedl) or that their development follows the withdrawal of the thymus secretion

It is highly probable that the thymus is intimately connected with the calcium metabolism, but it can hardly be as Biedl suggests, that the effect of its secretion is to cause calcium retention in the bones—although several investigators (Basch, Cozzolino Tarulli and Lo Monaco) have found that rickets follows thymectomy in young animals, an effect not confirmed by Paton—for the skeletal structures become much more heavily laden with calcium phosphate after puberty when the gland atrophies

The matter is one of considerable difficulty But if thymectomy leads to increased calcium excretion and bone softening the growth of the genital gland which promotes the excretion of calcium would not tend to improve matters unless—and this is possible—the development of the genital gland causes an increased secretion from the suprarenals which leads to calcium retention

Effects of Thymectomy on the Other Ductless Glands

No reliable work appears to have been done on these lines It is urgently needed in order to clear up many of the difficulties concerning the relation of the thymus to the general metabolism

THE RELATION OF THE SUPRARENALS TO THE GENITAL SYSTEM

These glands may be studied in the same way that we have already adopted—that is from a physiological and pathological standpoint

In pregnancy certain changes occur normally in the suprarenals So far as my own observations go these are confined to the cortex The cells of the zona fasciculata appear swollen and cloudy Some observers (Guieysse and Gottschau) have found that in pregnancy the zona fasciculata increases in thickness at the expense of the zona reticularis and medulla My own observations are in accord with this The zona reticularis does not increase at the expense of the zona fasciculata in pregnancy, as it does after oöphorectomy

Conflicting views as to the effects of castration have been put forward by Schenk, Cecca and others A source of error in the estimation of the thickness of the various zones is liable to arise unless care be taken to cut mesial sections, or, better still, serial sections

Effects of the Removal of the Suprarenals

In most mammals complete removal of the suprarenals causes death in from a few hours to a few days The animal does not eat, it sits very quietly gradually becomes weaker tremors occur, and death supervenes This course of events occurs so rapidly that as a rule no estimation can be made of the metabolism and any changes observable in other ductless glands must be of an acute character and of less value from a practical point of view than those which are obtained by the production of chronic insufficiency a condition difficult to bring about experimentally Acute results may, however be useful as indicating the trend of events

Many rats, owing to the fact that a large percentage of them have accessory interrenals consisting of cortical substance, are said to be able to survive extirpation of the main organs I have had no experience of extirpation experiments on these animals My investigations have been carried out on rabbits and cats Those animals from which both suprarenals were removed either at one or at two sittings died within 48 hours I tried therefore the effect of the removal of one suprarenal in the hope of being able to produce insufficiency, since we know the other suprarenal hypertrophies in these circumstances and shows a condition somewhat comparable with the hyperplasia of pregnancy Two cats gave negative results in regard to the metabolism but with two rabbits I obtained definite results One of the animals was destroyed at the end of 30 days as it was obviously dying It was much emaciated, its weight having dropped from 2000 grammes to 1400 grammes The post mortem notes run as follows "No cause of death found The site of the previous operation unrecognisable except for the absence of the gland "

The other rabbit died at the end of 127 days It also was greatly emaciated the weight having decreased from 1710 grammes to 1020 grammes At first the animal gained weight after the operation and then it steadily lost ground. No cause for death was found

These results are apparently of some value for according to most recent authorities unilateral extirpation in rabbits produces no symptoms

With regard to the metabolism we obtained very interesting records In each case a considerable increase in the excretion of calcium was observed (Table VI) In one case

TABLE VI —*Removal of Left Suprarenal Averages of Metabolism Estimations of 24 hours Specimen Urines*

TABLE VII —*Averages of Metabolism Estimations of 24 hours Specimen Urines from Two Rabbits Before and After Removal of Suprarenals*

—	Number of specimens examined	Specific gravity	Diacetic acid	Acetone	Albumin	Sugar	Indican	Ca %	Cl %	P_2O_5 %	Total N %	Urea %	NH_3 %	Ammonia coefficient Urea N %	 NH_3 N %	 Undet N %
Before operation	3	1020	0	0	0	0	0	0·0023	0·161	0·203	0·90	1·68	0·148	84·23	3·48	12 8
After operation	23	1028	0	0	0	0	4 times	0·0240	0·230	0·577	1·58	3·01	0·040	88·55	2·09	9·3

the average quantity excreted after operation was seven times as much as that excreted before operation. In the other case it was sixteen times as much. The average for the two cases was, of course, between these figures (Table VII.).

The excretion of phosphorus was much increased but not in the proportion one might have expected.

The urea excretion was increased out of proportion to the differences between the specific gravities before and after operation.

Now this increase of the calcium excretion is of very considerable interest, and I much regret not having a longer series of cases. It is well known that the view has been advanced that osteomalacia is due to insufficiency of suprarenal secretion, and Bossi first called attention to the beneficial results to be obtained by the injection of adrenin in these cases. I have not met with a case of osteomalacia in recent years, so I have had no experience of this treatment. But these experiments give very strong support to this view of Bossi, not only in the metabolism results, but in a most striking way in regard to the bones of one of these animals.

The bones of the forelegs—on which I presume a good deal of weight would fall—were found to be markedly bent. Fig. 11 shows the normal condition of the bones of the forelegs. Fig. 12 is a radiogram of the condition found in one of the rabbits. The bones of the back legs, which are thicker, were only slightly curved. But owing to the manner a rabbit sits very little weight would fall on these bones. I regret that a radiogram was not taken before operation, but I hardly think such curving could have escaped notice during the handling of the animal at an operation. And the boy who has charge of my animals, and, in fact, discovered the condition, is quite certain it followed the operation, and I can hardly understand how it could have been otherwise. It is to be remarked that it was in this animal that the largest quantities of calcium were excreted. This is, however, such an important case that I feel constrained to play the part of the devil's advocate in regard to it.

The bones of these animals were chemically examined and compared with the bones of normal animals, but I do not include the records here, as we have been unable to conceive any satisfactory way of interpreting the results. Bones deficient in calcium weigh lighter than bones that are rich in it. So that if we take a gramme of osteomalacia bone and estimate the quantity of calcium we would find much the same quantity as in the same weight normal bone. Again, the percentages of the constituents vary normally to a considerable extent according to the age of the animal and other factors.

Effects of Suprarenal Removal upon the Pituitary Body.

The changes that occur seem to be much the same whether the insufficiency be acute or chronic; thus in cat No. 1 of my series of suprarenal removals the glands from both sides were removed at the same time. There was an interval of 36 hours between operation and death.

The cells of the pars anterior show a marked degree of chromophobia with a moderate degree of faint eosinophilia. In many places the nuclei are very deeply stained with hæmatoxylin.

In the pars intermedia the cells are discrete—that is to say, they are not fused—and show no special activity; the nuclei stand out prominently.

The pars nervosa is freely invaded by the cells of the pars intermedia, but the nuclei only are prominent, as though they were left stranded after the disappearance of the cell cytoplasm.

Exactly similar changes were noted in rabbit No. 2, which showed such marked symptoms of suprarenal insufficiency, as already recorded. The anterior lobe showed very well the chromophobe cells, and the faint blurred character of the eosinophile staining.

Taking all the facts into consideration I hardly think we can come to any conclusion other than that the anterior lobe shows greatly increased activity. The pars intermedia is apparently not in an actively secreting condition, but the extensive invasion of the pars nervosa by pars intermedia cells and the immediate disappearance of the cell cytoplasm appears to indicate that an attempt is being made to counterbalance the loss of adrenin by the rapid production of infundibulin.

Effect of Removal of the Suprarenals upon the Thyroid.

I have been unable to trace any histological change either in acute or chronic suprarenal insufficiency.

Effects of Removal of Suprarenals on the Ovaries and Uterus.

There appears to be no histological change of importance in the ovary, but it is worthy of note that the normal eosinophilia of the zona pellucida is not decreased, rather if anything is it increased. After removal of one suprarenal, if insufficiency be produced, the uterus appears to undergo changes comparable with those that are seen after thyroidectomy, but the muscular atrophy appears to be less in extent; probably this is due to the state of incomplete insufficiency (Fig. 13).

Clinical Observations of the Effect of Pathological Lesions of the Suprarenals on the Genital System.

We meet with conditions in the human subject which represent both an under-secretion and an over-secretion of the suprarenals. This is decided on clinical and histological evidence. At the same time we are still in the dark as to the exact relationship of the cortex to the medulla.

In Addison's disease we have what are apparently the symptoms of insufficiency of medullary secretion, as is shown by the low blood pressure and general muscular weakness. But in this disease the cortex also is destroyed.

It is doubtful if sufficient pathological observations have been made with a view of observing changes in the ovary and uterus to enable us to give any definite statements regarding them.

Amenorrhœa is, I believe, usually associated with Addison's disease, but this may be due solely to the effects of a condition which produces general progressive enfeeblement. On the other hand, our experimental evidence indicates that atrophy of the uterus presumably with insufficiency of the function of the interstitial cells occurs in these circumstances.

The other pathological lesions which have been subjected to a good deal of attention lately are hyperplasia and tumour formation in the suprarenal cortex. For some years these lesions have been known to be associated with extraordinary changes in the primary and secondary sex characteristics. Attention was first called to these interesting phenomena by Woolley, Bulloch and Sequeira, and Neugebauer.

Last year my colleague Professor Ernest Glynn reviewed exhaustively the whole subject, and added five fresh cases in children to those already collected by Bulloch. Out of 17 cases in children, 14 were females. In these there were usually skeletal overgrowth, hair on the face and pubes, and sometimes hypertrophy of the clitoris. Further, Glynn collected six cases occurring in young adult females, in all of whom there was growth of hair on the face, shrinkage of the breasts, amenorrhœa, and sometimes a masculine voice. Pathologically, the suprarenal enlargement in the children and young adult females was unilateral and neoplastic in character, and directly or indirectly caused death. Metastases were sometimes found.

In a second group of cases there were 13 pseudohermaphrodites, 12 being females, and in these the suprarenal enlargement was bilateral, hyperplastic in nature, and there were no metastases.

Glynn suggested that in these cases hyperplasia of the suprarenal cortex occurred in fœtal life before the differentiation of the genital ducts, and led to the persistence of the Wolffian derivatives, thus causing female pseudohermaphroditism.

No sex changes are associated with tumours of the suprarenal cortex when they occur in adult males or in women after the menopause.

This body of pathological evidence is of great value, and it shows how closely the adrenal cortex, which is developed from the mesothelium of the Wolffian ridge adjacent to the germinal area, is connected with sex characteristics. How far the influence of the suprarenal cortex acts in conjunction with the sex gland is not known. Probably there is some correlation between them in normal circumstances.

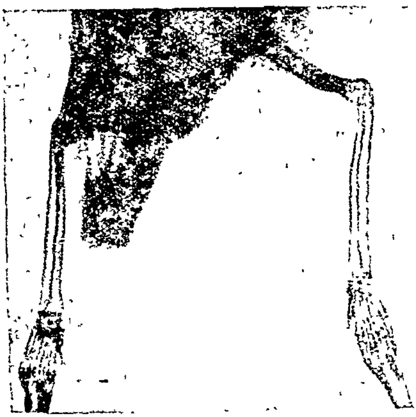
I now come to the last and, in some ways, the most difficult part of my task.

THE CORRELATION OF THE INTERNAL SECRETIONS IN REGARD TO THEIR GENITAL FUNCTIONS.

I have endeavoured to trace, for the most part from my own observations, the disjointed facts concerning the influences exerted by the different membe[illegible] upon one another and on the [illegible] as the genital system is conc[illegible] sometimes shown clearly the nature of the associations between the different organs.

But it is absolutely impossible at the present time to correlate fully all their functions, so that perhaps the less said now the less there will be to withdraw at some future date. In view, however, of what I said at the commencement as to the necessity for a lead in this intricate matter, I cannot refrain from enunciating what I believe to be the general principles. I shall not have time further to analyse the details.

FIG. 11.

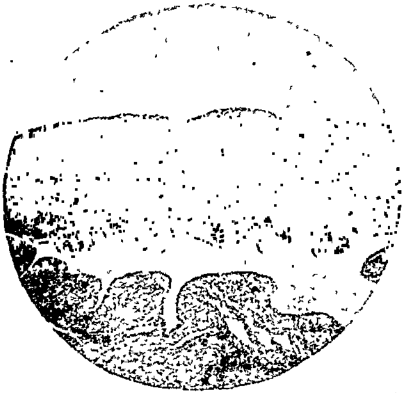


X ray photograph of the bones of the forelegs of a normal rabbit. ½.

It appears, from the evidence at our disposal, that in spite of great [illegible] ductless glands in [illegible] *It* is the same in [illegible] The variations in function that depend on the differences of structure are probably related to differences in the food and habits of life.

In adapting our knowledge to the requirements of human physiology and pathology we must take into account *both* the essential functions I have already referred to—the individual metabolism of the mother, and the metabolism of her reproductive functions—for they are completely interdependent.

FIG. 13.

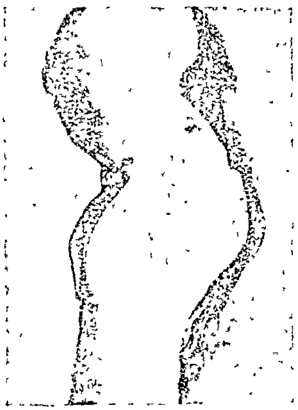


Uterus of a rabbit after unilateral suprarenal removal. Moderate degree of muscular atrophy. × 75.

We have seen as the result of our studies that the ovaries, on the one hand, have as their share of these dual functions the onus of ensuring the reproduction of the species, by furnishing the ova, and by keeping active the rest of the genital structures and functions And, further, the secretions of the ovary are *concerned* in keeping the other members of the ductless gland *system* in touch with the [illegible] importance, and is one which explains much that would otherwise be obscure.

When the reproductive functions cease and the ovaries atrophy at the menopause the harmony that previously existed between the general and the genital metabolism is temporarily deranged, and various disturbances may *ensue*. *And it is only* by the careful investigation of each menopausal case that one can arrive at a determination of the manner *in* which the balance has been upset. It is impossible always to alleviate the symptoms, *but the basis of* treatment rests on the regulation of the existing disarrangement by the administration of the necessary secretions. Some patients react to thyroid extract, some to pituitary, others, again, to combinations, so great are the individual variations. In most cases a natural readjustment takes place in the course of time.

FIG. 12.



X ray photograph of the bones of the forelegs of a rabbit after unilateral suprarenal removal. ½.

So that, strictly speaking, the ovary is only concerned in [illegible] the ovary has been supposed to be responsible for the beauty of the vessel by means of which its ends are to be attained. But to-day we are beginning to wonder how far the ovary does influence secondary sex characteristics, and whether full individual secondary characteristics can be obtained by the influence of the ovary alone.

We have evidence that hyperplasia of the suprarenal cortex can upset any influence the female genital gland may be supposed to possess, and can produce in a female some of the secondary characteristics of the male, and even partially change the genitalia to complete the picture.

I well remember seeing a case under the care of Dr. Russell Andrews. The subject possessed every female characteristic except for the absence of uterus, Fallopian tubes, and ovaries; instead there were testes within the abdominal cavity. This individual was a male pseudo-hermaphrodite with the pure secondary characteristics of a female, and a prepossessing one at that. Such a condition could not have existed with hyperplasia of the suprarenal *cortex*; indeed, it is probable there was hypoplasia.

Any influence the ovary has over the general metabolism is, then, related to and dependent on its primary reproductive function. I do not believe that it influences the metabolism except in so far as this special function is concerned. Of course, removal of the ovaries may produce a temporary disturbance, but this has already been explained, and does not invalidate the view just mentioned.

On the other hand, the rest of the ductless gland system is related to the genital functions in various ways. Firstly, some of the members—the thyroid, pituitary, and suprarenals—influence the development and subsequently preserve the integrity and activity of the genitalia, as I have already demonstrated. Others—the thymus, and possibly the pineal—appear to prevent sexual precocity. Secondly, all the ductless glands control the metabolism in response to the necessities of the genital functions. But, in addition, they adapt the whole organism to the possibility of the situation, and regulate the secondary characteristics, both physical and psychical, to suit the needs of the individual. Once, however, the reproductive organs are removed or undergo atrophy, the primary genital functions of the rest of the ductless glands cease, and the rearrangement of the metabolism that follows produces what are known as the symptoms of the menopause. Contrariwise, insufficiency of the thyroid, pituitary, or suprarenals causes the cessation of the genital functions with atrophy of the uterus.

As to the more particular parts played in the metabolism by each member of the ductless gland system, these have already been specified.

In spite, therefore, of the reluctance to correlate our knowledge shown by most investigators the matter is not one of very great complexity if my views be correct in a general way, although there remains much detail to fill in.

As soon as possible we must come to a conclusion as to what are the facts; so much work that has been done is contradictory. There is, therefore, so much more the need for further efforts.

In concluding, I would again insist that in order to solve completely the problems surrounding the genital functions, we must focus at one and the same time the two essential processes of life—the individual metabolism and the reproductive metabolism. They are absolutely interdependent. Indeed, the individual metabolism is the reproductive metabolism. It is the neglect of this point of view that has brought about much of the confusion that exists.

Weismann and Ray Lankester describe the relation between the reproductive cells and those of the soma in still more striking terms. The latter says: "Among the multicellular animals, certain cells are separated from the rest of the constituent units of the body, as egg-cells and sperm-cells; these conjugate and continue to live, whilst the remaining cells, the mere carriers as it were of the immortal reproductive cells, die and disintegrate. The bodies of the higher animals which die may from this point of view be regarded as something temporary and non-essential, destined merely to carry for a time, to nurse and to nourish the more important and deathless fission products of the unicellular egg."

Whatever views we may hold as to details I question whether this philosophical statement is open to contradiction. The function of reproduction in all its preparations and performances commences in the early stages of segmentation, and may be said to continue in man until the care of the offspring is completed. In many insects, male and female, the act of reproduction is also the cause of death.

Evolution and the pressing necessities of individual life have led men to look upon the function of reproduction as of vastly inferior importance to their own individual metabolism. No doubt women will soon come to think so too, for they seem to be changing. Whether this change be due to an increasing hyperplasia of the female suprarenal cortex I do not know. But just as we are beginning to think that our knowledge of their special functions is becoming well defined they invite us to follow their further evolution, which apparently they think will not involve them in the joys of motherhood.

Helmont said: "Propter *solum uterum* mulier est quod est." Chévau changed this to "Propter *ovarium solum* mulier est quod est." Virchow reiterated this statement and, according to Biedl, added that "all the peculiarities of her body and mind ...... everything, in fact, which in the true woman we admire and revere as womanly, is dependent on the ovary."

In the light of our present knowledge I venture to think that the following aphorism most accurately represents the cause and effect: "Propter *secretiones internas totas* mulier est quod est."

The original work detailed in these lectures, which were illustrated with many photomicrographs and colour photomicrographs, was carried out in the Bio-chemical and Pathological Laboratories in the University of Liverpool; and I am much indebted to Professor Benjamin Moore and Professor Ernest Glynn for help in various directions, and especially for the facilities accorded to my assistants, and for the superintendence of their work.

The entire expenses were defrayed out of the J. Arthur Smith Research Fund.

The Lumleian Lectures

ON

INTRATHORACIC ANEURYSM.

Delivered before the Royal College of Physicians of London on March 6th, 11th, and 13th, 1913,

BY F. DE HAVILLAND HALL, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE WESTMINSTER HOSPITAL.

LECTURE III.*

Delivered on March 13th.

MR. PRESIDENT, FELLOWS AND GENTLEMEN,—The *prognosis* in intrathoracic aneurysm must always be a most anxious one. I would hardly like to say that a complete cure is impossible, but with one or two doubtful exceptions—I say doubtful, because the cases were observed before the X ray method of examination was introduced—I have not seen a case which I could consider a permanent cure.

Treatment by rest and other measures will usually remove pain and other unpleasant symptoms, and cause a great modification in the physical signs; but, as is often shown by the post-mortem examination, while the original aneurysm has become consolidated, another aneurysm has developed, and this, which frequently escapes recognition, may be the cause of death. As might have been expected, an aneurysm progresses less quickly in people who can lead a quiet life and who are of a placid disposition. It has been stated that aneurysms run a more rapid course in women than in men, but I have not been able to verify this statement. The presence of aortic regurgitation is a very unfavourable sign, as is also advanced degeneration of the blood-vessels.

To show the frequency of sudden death in aneurysm I may quote Dr. Kelynack's statistics; out of 32 cases of rupture reported by him six were observed in medico-legal investigations, the subjects beings brought dead to the hospital. Six of my 35 private patients died suddenly, in addition to 6 who died from rupture of the aneurysm, 4 of whom are definitely stated to have died suddenly, and possibly the other 2 also may have died suddenly.

The duration of life after the recognition of an intrathoracic aneurysm is, in my experience, usually limited to less than 4 years, though in very exceptional cases life may be prolonged for 6 or 7 years.

I have carefully investigated the notes of 35 cases of aneurysm I have met with in private practice. Excluding all doubtful cases and cases in which I have not been able to trace the final result, and excluding also a patient who was alive 10 years after I had made a diagnosis of aneurysm, I find that the average duration of life in 27 cases works out to a little over 2 years and 8 months. There are 2 cases in which death apparently occurred nine months after the appearance of symptoms suggestive of aneurysm, and 1 case in which death was delayed for seven years. Owing to the extreme difficulty which often presents itself in fixing the exact date of the onset of symptoms, I feel convinced that my figures underestimate the duration of life, and I think that about three years would be nearer the mark. In some cases the symptoms of the aneurysm started so definitely after a well-recognised strain that one can be quite sure as to the duration. In one patient who was under my observation nearly the whole time the strain occurred four and a half years before death.

All my 27 cases occurred, as I have already stated, in my private practice; they were almost all of them sufficiently well endowed with this world's goods to be able to take care of themselves, as in every case they had been warned of their condition; and as all the cases had been submitted to treatment more or less carefully carried out, it was to be expected that they would last longer than hospital patients, who generally have to resume work when quite unfit for any active exertion.

Sir William Osler[1] states that "the average duration after discovery is from 18 months to 2 years," but he does not mention from what class of patients his statistics are derived.

A case I showed at the Medical Society[2] in April, 1911, illustrates the slow progress of some cases. The patient was a man of 43 years of age, a wire-drawer. He was originally admitted into Westminster Hospital under my care in July, 1905, placed on low diet, kept at absolute rest, and given iodide of potassium in moderate doses. He improved greatly under treatment, but has taken iodide off and on ever since. He was able to continue at work—fairly laborious—the whole time. In March, 1910, he had a slight attack of hæmoptysis. When shown to the society the physical signs of an aneurysm of the first part of the arch of the aorta were very distinct.

A somewhat similar case is recorded by Dr. Gibson.[3] The patient was a man, 39 years of age, whose occupation involved a very considerable amount of physical exertion, who lived for 12 years after the diagnosis of an aneurysm of the ascending portion of the arch of the aorta, and who died eventually from heart failure. On two occasions he was an in-patient, and was treated by means of absolute rest, restricted diet, and iodide of potassium.

The most remarkable instance of the preservation of life under threatening conditions which I have come across is a case reported by Dr. T. R. C. Whipham.[4] A man, 40 years of age, was admitted into hospital with a rounded tumour in the first and second right interspaces, the skin over it being tense and discoloured. He was under observation for full 15 years, and during the whole of that time he had a large external tumour, though the aneurysm had probably existed a year or so longer. With the exception of about 18 months spent in hospital the patient was able to carry on his occupation of builder's foreman. Death occurred from external rupture of the sac.

These three cases afford good examples of the great difficulty which often attends the prognosis in cases of aneurysm.

LIFE ASSURANCE.

My experience in life assurance has taught me that thoracic aneurysms are not infrequently overlooked, and that consequently they represent one of the causes of early death after assurance.

In a paper I read before the Life Assurance Medical Officers' Association in 1907[5] on Statistics of the Rock Life Assurance Company I made the following remarks:—

> There were 6 deaths from aneurysm of the thoracic aorta and 1 from aneurysm of the abdominal aorta. In addition to these cases there were 3 deaths recorded from rupture of the aorta—these were probably due to aneurysm. Two of the claims due to death from [illegible]
>
> experience will know how difficult is the diagnosis of an aneurysm, [illegible]
>
> life assurance.
>
> Taking the 10 cases of aneurysm and rupture of the aorta together, the average age at entry was 51·5 years, with an average duration of [illegible]
>
> aortic area.

These remarks, made five years ago, are in accord with my present views on the subject.

MEDICAL TREATMENT.

While I was attending the practice of St. Bartholomew's Hospital I was much impressed by the teaching of the late Dr. James Andrew, whose great diagnostic skill and general excellence as a physician were universally admitted by all who had the privilege of working with him in the wards of the hospital. He was particularly keen on the recognition and treatment of intrathoracic aneurysm.

Tufnell's Method of Treatment.

Dr. Andrew was one of the first in London to adopt cent. solution may be used at first without unfavourable symptoms. Occasionally the injection is followed by smart reaction, the patient may have a rigor, and his temperature may rise to 103° or 104° F. Though very alarming at the time no evil may result from it. When this plan of treatment was first introduced into this country two deaths from tetanus occurred, but if the gelatine be carefully sterilised, and strict aseptic precautions be taken in carrying out the injection, the risk of tetanus may be regarded as *nil*.

---

* Lectures I. and II. were published in THE LANCET of March 22nd (p. 803) and 29th (p. 869), 1913, respectively.

As regards the results obtained by the gelatine plan of treatment, it may be said that though benefit has resulted in a considerable number of cases, it has not justified the claims that were made on its behalf when it was first introduced, as there is no definite evidence of the cure of a thoracic aneurysm by this means. The two classes of cases in which its employment seems particularly indicated are cases in which an aneurysm has perforated the chest, and in which there is a danger of external rupture, and cases in which there is great pain.

The calcium salts, such as the chloride and lactate, have been employed in the hope that they would favour coagulation of the blood in the sac, but I have not been able to discover any evidence that they have a beneficial action—with the exception of a case mentioned by Dr. Oswald Browne in the discussion on Aneurysm at the Medical Society of London in 1900.

Expectant and Symptomatic Treatment.

Lastly, there comes the purely expectant and symptomatic method of treatment. Some physicians are altogether opposed to the rest cure; they maintain that patients who are subjected to it are worse at the end of the treatment than when it was started, because their tissues had degenerated during their passive existence, and that they were consequently less able to resist disease.

Confinement to bed on a very spare diet has a most depressing effect upon some people, and therefore the cases which are to be submitted to this line of treatment should be selected with the greatest care, as I have already pointed out, not only in regard to the physical state, but also as regards the mental condition. To say that a patient with an aneurysm leaves the hospital, after a rest cure with a modified Tufnell diet, in a worse case than on admission, is not in accord with my experience, now extending over more than 40 years. Still, there are quite a number of patients with intrathoracic aneurysm who do better physically, and certainly mentally, if they are allowed to pursue their ordinary avocations, provided their work be not too strenuous for body or mind. We all must have met men who, when their grave condition has been clearly placed before them, have elected to continue their life work at all risks, and I am bound to say that my sympathy is with them, and that I myself would, under similar circumstances, feel inclined to follow their example.

In the event of a patient deciding to lead his ordinary life, he should be cautioned to take things as easily as possible, to avoid all great exertion, especially of a sudden nature, to eat with great moderation, and, as a general rule, to avoid alcohol. Tobacco may be indulged in with moderation, and by moderation I mean a quantity of tobacco not exceeding three ounces per week.

Medicinally, I have no doubt that these patients are benefited by iodide of potassium, especially if the blood pressure be high. I usually order from 5 to 10 grains with 15 to 20 minims of aromatic spirit of ammonia in chloroform water to be taken three times a day after food. This will often suffice to keep them comfortable.

For the relief of the agonising pain that is sometimes experienced in aneurysm no remedy has a more remarkable effect than bleeding. Dr. Pye-Smith's[14] experience on this point is decisive. He writes as follows:—

> I shall never forget the case of a man who for more than a week had not been able to lie down or enjoy more than broken and uninterrupted (*sic*) sleep. I found him the day after his admission to the hospital sitting up in bed, exhausted by want of rest and continually dropping asleep, but wakened again by the terrible pain he endured. The house physician had given him morphia in full doses without any benefit. He was bled from the arm to 6 oz., and before the blood ceased flowing expressed the relief he felt, and had fallen fast asleep on his pillow before the arm was bound up. His distress was never suffered to reach so advanced a point, and again and again *on its return* he was relieved by a similar or a still smaller abstraction of blood.

One such case is quite sufficient to prove the utility of venesection for the relief of the awful pain occasionally suffered by the victims of aneurysm. Venesection is to be preferred to leeches in these cases, as the relief experienced is more rapid and complete.

The application of an ice-bag suspended from above so as to avoid too much pressure upon the tumour will often have a beneficial result upon the pain.

For the relief of the anginal attacks met with in aneurysm iodide of potassium in 10 to 20 grain doses three times daily will usually effect much good. In cases where the iodide fails liquor arsenicalis in 5 minim doses three times a day will sometimes be found useful. For the acute anginal attacks the inhalation of nitrite of amyl, followed up by the internal administration of trinitine, is generally efficacious. Erythrol tetranitrate, in ¼ to ½ grain doses, may be given instead of trinitine, especially if the duration of the attacks be protracted. But in many cases there comes a time when the only drug to give relief is morphine subcutaneously. I prefer to give it in combination with atropine. I am of opinion that the atropine counteracts some of the injurious effects of the morphine and prolongs its action.

For the treatment of dyspnœa, especially when accompanied by lividity, there is no remedy which can be compared to the abstraction of blood. The blood may be removed either by venesection or by the application of leeches. The over-distended condition of the right heart is often greatly benefited by loss of blood, when there is pressure on the veins causing great venous engorgement.

Should an aneurysmal tumour on the surface of the chest begin to weep and ooze, the best application is styptic lint, kept in position by a broad piece of strapping, but, of course, this can only temporarily check the tendency to rupture.

TRACHEOTOMY.

There is one question in regard to treatment which occasionally presents itself in a most dramatic form—viz., whether tracheotomy should be performed for the relief of paroxysmal and urgent dyspnœa?

In this connexion the older Fellows of the College will doubtless recall the case of the Earl of St. Maur. This case occurred before the laryngoscope was commonly employed in this country, but what Dr. C. J. B. Williams[15] wrote upwards of 40 years ago is still true to-day. After speaking of the life-saving effect of tracheotomy in cases of laryngeal obstruction, he goes on to say:—

> It is different with the dyspnœa caused by *intrathoracic tumours.* These produce not only *laryngeal* dyspnœa by pressure on the recurrent nerves which regulate the motions of the glottis, but also
> *tracheal* ssure on the lower part of the windpipe
> itself. reathing may be due to the pressure on
> the ner may be relieved by the operation for a
> time; but that proceeding from direct pressure on the windpipe is beyond the reach of that or any operation, and if this direct pressure exist to any great degree it would render the operation fruitless.
> Further, it must be borne i
> of intrathoracic tumour, m
> and in other ways besides
> case tracheotomy cannot be regarded in the lig
> Its power to give temporary relief will depend on how much the difficulty of breathing caused by the aneurysm is *laryngeal*, from pressure on the recurrent nerves only, and not *tracheal or bronchial*, from pressure on the windpipe or one of its branches. When there is time and opportunity for careful examination, these distinctions may be made from the character of the physical signs, so as to determine beforehand whether the operation is likely to be beneficial or not.

I have ventured to quote at length the wise remarks of Dr. Williams, and which, though written in the pre-laryngoscopic days, still in the main hold good.

In the discussion at the Medical Society in 1900,[16] on the Diagnosis and Treatment of Intrathoracic Aneurysm, I propounded the question "For what conditions should tracheotomy be advised in cases of aneurysm of the arch of the aorta?" As my contribution to the discussion I then said:—

> gathered from
> ut rarely that
> n. The chief
> trachea, even
> r paralysis of
> the abductors of the cords.

I also mentioned two cases in which I had been called in at the last moment, and in both I had decided that tracheotomy would not give relief. Both these patients died the day after I saw them, and at the necropsy there was found to be direct pressure on the trachea, and this was evidently the cause of the dyspnœa.

Sir William Broadbent, in the course of this discussion, said that "he had seen tracheotomy done, but without influence on the symptoms" On the same occasion Sir James Kingston Fowler mentioned the case of a man who had bilateral abductor paralysis from pressure of an aneurysm, and as a result suffered from most severe paroxysmal attacks of dyspnœa Tracheotomy was performed between the attacks, and the patient, who had had no sleep for two and a half days, went to sleep immediately after the operation, and slept for nearly 24 hours continuously

Of course, there can be no doubt that if the dyspnœa be due to spasm of the adductors or paralysis of the abductors, then tracheotomy will be an immense relief to the patient, on the other hand, tracheotomy is useless in cases of direct pressure on the trachea But it is in cases of a combination of these two conditions—i e, where there is a double stenosis of the air passage, due to bilateral paralysis of the abductors and direct pressure on the trachea—that the great difficulty as to the advisability of tracheotomy arises In these cases the respiratory excursions of the larynx will help in deciding In two cases in which I was called in, at the last moment, to decide whether tracheotomy should be performed I decided in the negative on account of the absence of respiratory excursions of the larynx Where the obstruction is at the glottis there is an up and down movement of the larynx, but where the obstruction is in the trachea this is absent I think that the correct attitude to assume in these cases of double stenosis is to advise operative interference in the hope that the laryngeal condition is the chief cause of the dyspnœa In this event the tracheotomy will add much to the patient's comfort If, on the other hand, the pressure on the trachea be the principal cause of the trouble, then tracheotomy will be practically useless, as it was in the case of Earl St Maur, but the operation would add but little to the patient's distress

The possibility of passing a stiff rubber tube down the trachea, beyond the obstruction, should be borne in mind—an early example of this procedure is afforded by a case recorded by Sir J R Bennett[17] The patient was a man under Mr Bryant's care at Guy's Hospital with a goitrous like tumour pressing on the trachea Tracheotomy was performed, but no air passed out of the chest A long perforated tube was then introduced through the cannula into the bronchus when a rush of air immediately followed and was succeeded by natural respiration

My present attitude towards tracheotomy is in favour of the performance of the operation in doubtful cases The patient may receive only temporary benefit, but we substitute a quiet death for one attended with great suffering To avoid the unpleasant sequel of Earl St Maur's case the [illegible] before the patient's friends the [illegible] it that tracheotomy offered a [illegible] it might only be very partial should there be any mechanical pressure obstructing the *trachea at a lower level*

Before resorting to tracheotomy in cases of paroxysmal dyspnœa the administration of chloroform might well be tried If it relieved the patient operative interference would be uncalled for, but if not, then the operation could be carried out all the easier for the anæsthesia, and artificial respiration resorted to if necessary Even after the performance *of tracheotomy the administration of chloroform* may be necessary to relieve the spasmodic attacks of dyspnœa due to irritation of the vagi

SURGICAL TREATMENT

The surgical treatment of intrathoracic aneurysm may be considered under five heads (1) the ligature of the great vessels arising from the innominate artery or arch of the aorta, (2) the passing of wire—filipuncture—into the aneurysmal sac with or without the passage of a galvanic current through the wire, (3) galvano puncture; (4) Macewen's method of needling, and (5) the ligature of the neck of the aneurysmal sac

Ligature of Vessels

The treatment of thoracic aneurysm by ligature of vessels is not a subject on which I have much personal experience Even among surgeons there is considerable difference of opinion as to the advisability of the operation In a case of aneurysm of the arch, in which Mr Christopher Heath[19] tied the left common carotid, he maintained that the aneurysm was practically cured at the time of death, and that the fatal termination of the case was due to the pressure effects of the consolidated tumour. At the meeting of the Clinical Society when this case was discussed Mr. *Howard Marsh mentioned that in one case in which he tied* the right common carotid and subclavian arteries for aneurysm of the arch, it appeared that the operation made the patient worse instead of better, for the sac rapidly enlarged On the other hand, Mr Holmes, in his lectures delivered before the Royal College of Surgeons of England in 1872, mentioned 7 cases in which the left carotid was tied for *aneurysm of the arch, 4 of these cases were successful, and* all except one derived benefit from the operation

The chief indication for the ligature of the carotid and subclavian vessels is pain, while aortic regurgitation and [illegible] are unfavourable to operation [illegible] with Mr Christopher Heath's[18] [illegible] es in which he tied the left *carotid*

> The results taken as a whole, are perhaps not very encouraging, but it must be borne in mind that in dealing with a practically incurable disease a prolongation of life for even a few months may be worth attempting

Introduction of Wire into Aneurysmal Sac

The introduction of wire into the sac of an aneurysm—*Moore's method*[?]*—has received from M Verneuil the name* of "filipuncture" Though this operation has been attended with very unsatisfactory results in aneurysm of the arch of the aorta, it has been more successful in abdominal aneurysm I have seen only one case in which this treatment has been carried out The patient was under the care of my colleague, Sir Bryan Donkin[21] Mr Macnamara passed a yard of *silver wire into the sac through a curved tubular* needle The man died six days after the operation In 1887 Sir Alfred Pearce Gould[22] operated on a patient of Dr W H White The case terminated fatally on the sixth day from sloughing of the tissues In his report on this case Sir Alfred Pearce Gould mentioned six other cases of aortic aneurysm which had been treated by the introduction of watch *spring or steel wire All the cases ended fatally, but* in one there was temporary improvement

Until the year 1903 the method of wiring was unscientific and was carried out with comparative disregard of aseptic principles In this year Mr G H Colt invented an instrument for the rapid introduction of a known quantity of sterilised wire into an aneurysm, with a minimum of disturbance He has described and figured an improved instrument (No 3)[23]

Dr Dawson Turner's[24] experiments would suggest that surgeons should employ zinc wire for introduction into the aneurysm, which they intended to treat by electrolysis rather than silver or other kinds of wire, a larger and a firmer precipitate being deposited by this means

A full account of the results of the method of treatment by wiring, with or without electrolysis will be found in the discussion which took place at the Surgical Section of the Royal Society of Medicine in May last Mr d'Arcy Power's[25] conclusions at this discussion are so much to the point that I will quote them *in extenso* —

> The chief indications for the operation of wiring are: 1 An [illegible] re; 1 Rapid increase of pain or of [illegible] probably indicative of an early and [illegible] ptoms pass away under treatment the [illegible] ain considered 2 The presence of a [illegible] part of [illegible] at the [illegible] place in [illegible]

Professor A A Eshner[26] has collected the records of 36 cases in which an aortic aneurysm has been treated by the introduction of wire into the sac and the passage of a galvanic current through the wire *In 19—i e, in about* half the cases—death followed within a month of the wiring, the best result being that obtained by Professor Rosenstirn, whose patient lived nearly 12 years after the operation One of Professor Eshner's patients lived four weeks, the other a little over seven months

The risk run in passing wire into the sac of an aneurysm of the arch of the aorta is well illustrated by a case treated by Mr. H. A. Ballance.[27] He introduced silver wire into the sac, and passed an electrolytic current through the wire. The patient lived ten months after the operation in comparative comfort. At the necropsy loops of silver wire were found in the sac, and loops of wire had also passed along the arch of the aorta, as far as the origin of the left common carotid artery and down to the bottom of the left ventricle. It is certainly very remarkable that a foreign body was tolerated in the heart so readily and for so long a period.

A careful consideration of the prospects afforded by wiring an aneurysm, with or without electrolysis, has convinced me that the operation, though quite justifiable in cases of abdominal aneurysm, cannot be of nearly the same service in cases of intrathoracic aneurysm. In the former case the surgeon can cut down and expose the aneurysmal sac, and can form a fairly clear idea as to the amount of sacculation present, and the operation, moreover, can be carried out when the wall of the sac is still in a satisfactory condition. In the case of an intrathoracic aneurysm the surgeon would, indeed, be a bold man who would propose to submit to surgical treatment an aneurysm which had not definitely come to the surface. By the time that this has occurred there is almost invariably a thinning of the sac wall and the risk of rupture. In addition the surgeon cannot satisfy himself that the wire has filled the sac. I expect, therefore, that in cases of intrathoracic aneurysm the operation of wiring will be more or less confined to those desperate cases in which there is a definite pulsating tumour on the chest wall, with the prospect that at no distant date external rupture will occur. If wiring succeeds in prolonging life in even a small proportion of these cases, and very occasionally effects an apparent cure, then I think that the surgeon may reasonably claim that he has done all that could be expected of him.

Galvano-Puncture.—Formation of White Thrombi by Needling.—Ligature of Neck of Sac.

I should feel inclined to restrict the use of galvanopuncture to cases in which the aneurysm has made its way through the ribs or costal cartilages, and where external rupture appears imminent. Cases of this sort have from time to time been recorded in which life has been prolonged in rapidly progressing cases, relief has been afforded to cough, paroxysmal pain, and pulsation, and finally death has taken place slowly and painlessly from gradual oozing from the thickened sac instead of by sudden rupture.

Sir William Macewen,[29] in a paper read before the Midland Medical Society in 1890, advocated the cure of aneurysm by inducing the formation of white thrombi within the sac. The instrument he employs is a cylindrical pin, tapering to a point, like an ordinary sewing needle, with rounded head at the other extremity. He gives the following directions for carrying out the treatment :—

> Before performing the operation the skin over the aneurysm ought to be carefully cleansed and rendered aseptic. The aseptic pin ought then to penetrate the sac and pass through its cavity until it comes in contact with the opposite side. It ought to touch and no more. Then one of two methods may be employed—either to move the pin over the surface of the inner wall so as to irritate its surface, or to allow the impulse of the blood-current playing on the very thin pin to effect the same object. ...... After acting thus for ten minutes at one part the point of the pin, without being removed from the sac, ought to be shifted to another spot, and so on until the greater portion of the internal surface opposite to the point of entrance has been touched; this ought to be done in a methodical manner.

The pin should be allowed to remain in a few hours, though it has been kept in for 24 or even 48 hours. The operation may require to be repeated on several occasions at intervals of about a week. In his original paper[29] Sir William Macewen reports 4 cases—2 of intrathoracic aneurysm, 1 of the abdominal aorta, and 1 of the right femoral. One of the intrathoracic cases and both the remaining cases were apparently cured by the treatment. In the case of the aortic aneurysm which died, at the necropsy the sac contained a large amount of firm white thrombi. Death in this instance occurred from asphyxia due to pressure of the aneurysm upon the trachea.

Though many theoretical objections might be alleged against this plan of treatment, the cases which Sir William Macewen brought forward, though few in number, are so striking that I am astonished that it has not received more attention at the hands of surgeons. Sir William Macewen wrote to me on this subject on Sept. 9th, 1912, as follows :—

> I have had numerous successes since (i.e., 1890), patients living for many years and working as before, with care however.

Mr. Gilbert Barling[30] in his remarks at the discussion on the Surgical Treatment of Aneurysm, on the three principal forms of surgical treatment adopted in the case of aortic aneurysm, did not take an optimistic view of these methods.

> He had never tried the introduction of wire, but he had tried electrolysis, and had been deeply disappointed with it, so that he was not likely to try it again. He had tried the operation of needling, but he did not think that the patient was either better or worse, and he was disappointed at the absence of improvement.

I think it doubtful whether surgeons in the future will attempt direct surgical interference in a case of thoracic aneurysm, but in view of the enormous strides that surgery has made of late years it seems impossible to limit their power of giving relief, if not cure. As an example of what has been attempted I may quote a case put on record by Tuffier.[31] The patient was a woman suffering from sacculated aneurysm of the first part of the arch of the aorta. As she was not more than 40 years of age, was in perfect general health, and was in imminent danger of rupture of the sac, Tuffier determined to ligature the sac close to its insertion into the aorta. This was done, but the aneurysmal sac was not removed. The omission was unfortunate, as the patient, who did well for some days after the operation, died on the thirteenth day from secondary hæmorrhage, due to gangrene of the sac and infection at the seat of ligature.

And here I must leave the question of the surgical treatment of thoracic aneurysm in the hands of the surgeons, hoping that in time to come they may be able to formulate some definite suggestions as to what kind of surgical interference is desirable and in what circumstances it should be adopted.

In concluding my lectures, I would again like to say how much indebted I am to Dr. Hugh Walsham for his generous assistance in putting at my disposal his large experience in the radiography of aneurysm, and I have also to thank most warmly Dr. Braxton Hicks, assistant pathologist at the Westminster Hospital, for his careful investigation of the post-mortem records of the hospital, which enabled me to make use of the valuable information therein contained.

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting will be held at Stafford on April 25th and 26th, when a discussion will take place on the Milk and Dairies Bill, to be opened by Dr. George Reid, county medical officer of health, Staffordshire County Council. Among those who are expected to take part in the discussion are Mr. T. W. H. Garstang, Dr. G. Petgrave Johnson, Dr. A. B. McMaster, Dr. Thomas Orr, Dr. H. Peck, Mr. T. Robinson, Dr. James Wheatley, and Dr. Meredith Young. The chair will be taken at 7.30 P.M. on Friday, April 25th, by Dr. Louis C. Parkes. Tickets for admission of visitors may be had on application to Dr. Reid, county council offices, Stafford, or to the secretary, 90, Buckingham Palace-road, London, S.W.

NON-PARASITIC CYSTS OF THE LIVER.

BY SIDNEY BOYD, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN AND TO THE MILDMAY HOSPITAL, BETHNAL GREEN; LECTURER ON APPLIED ANATOMY, KING'S COLLEGE.

NON-PARASITIC cysts of the liver are of uncommon occurrence, and the literature dealing with them, especially with large solitary cysts, was until recent years decidedly scanty. From a practical point of view these cysts may be divided into two classes—i.e., general cystic disease and solitary cysts. This classification is adopted by Bland-Sutton,[1] and although there is a good deal to be said for it, it has disadvantages, which will be referred to later.

General Cystic Disease.

General cystic disease is almost constantly associated with cystic disease of the kidneys, and rarely also of the pancreas, lungs, spleen, and brain. Out of 85 cases collected from the literature, Moschcowitz[2] found that the liver was affected alone in only 10. The condition may be found in children, but frequently it does not develop until adult life. There is a typical specimen in the Museum of the Royal College of Surgeons of England from a woman aged 46, which is figured in Bland-Sutton's book on "Gall-stones and Diseases of the Bile-ducts."

In the slighter forms of the disease the cysts are generally found just beneath the liver capsule, but when the condition is well marked the whole organ is affected and may be enormously enlarged. The general shape of the liver is preserved, but the cysts may project on its surface. The size of the cysts varies from a microscopic acinus to a cavity of the size of a pigeon's egg or larger. Absorption of the wall between adjacent cysts may occur, and often in the larger ones the remains of septa can be seen. Microscopically the cysts are found to be lined by a layer of epithelium, which is columnar in the smallest cysts, but as the cavity increases in [illegible] portal spaces.

The contents of the cysts are usually clear, watery fluid, sometimes yellowish-brown in colour. The fluid contains albumin, mucin, cholesterin, epithelium and granular débris. No bile or bile-pigment is generally present.

In an early case, besides the macroscopic cysts one generally finds on microscopic examination a greater number of bile-ducts than are normally present in the liver. These are mostly situated in the portal canals, surrounded, like the other structures in the canal, by a prolongation of Glisson's capsule, and are hence spoken of as being intracapsular. Thus, instead of a normal single duct, as many as six may be present. A few ducts may also be found in the lobules, where normally they are never found. On section they appear as round, oval, or tortuous acini, lined by cylindrical or cuboidal epithelium. These supernumerary ducts are believed by Moschcowitz[3] to be aberrant bile-ducts of congenital origin, and their development into cysts is believed by him to be the cause of general cystic disease.

Moschcowitz discovered aberrant bile-ducts in the liver of a fœtus unaffected by cystic change. There were also present cystic kidneys, a meningocele, and supernumerary fingers and toes. The whole liver was permeated with a system of ducts, intracapsular and intralobular, having no connexion with the liver cells. Kilvington[4] also examined the liver of a stillborn child showing many congenital defects, including cystic kidneys, and found numbers of [illegible] Moschcowitz. [illegible] the primitive [illegible] anching tubes [illegible] regards these aberrant ducts as a hypoplastic condition due to persistence of an embryonic state. It may be remarked here that small cæcal diverticula from the bile-ducts are commonly found in normal livers. Proliferation of the intrahepatic bile-ducts occurs in cirrhosis of the liver, as was first pointed out by Janowsky.[5] In the cases we are considering, however, there is no cirrhosis present, and, moreover, cysts are very uncommon in cirrhosis.

Fig. 1 is taken from a microscopic section of a liver from a body in the anatomy rooms at King's College, in which a small cyst of the size of a cherry was situated in the right lobe just under the capsule. Besides the larger cyst, several smaller ones were present, and in addition a number of aberrant ducts. Fig. 2 is taken from a section of a piece of the same liver near the portal fissure; it also shows a group of aberrant ducts.

As long ago as 1856 attention was drawn to general cystic disease of the liver by Bristowe,[6] who showed a specimen of this condition before the Pathological Society of London. The cysts are described as being scattered throughout the liver, arranged either singly or in clusters of two, three, four, or more. The larger ones were irregular in shape from fusion of adjacent cysts, and the remains of septa could be seen. The contents are described as thin colourless transparent serum. Microscopically, the cysts are described as consisting of fibrous tissue lined by flat epithelium.

In the same year Beale[7] showed specimens in which he injected the portal vein with size and the bile ducts with Prussian blue. In two or three cases the injection escaped from the ducts into the cysts by rupture of their walls, but there was apparently no free connexion between the cysts and the normal ducts of the liver. There was no dilatation of the ducts, nor could any obstruction be made out. Many smaller cysts were found in the central part of the lobules, and therefore some distance from the ducts. The cysts were thought to arise by degeneration of liver cells.

In 1898 Still[8] brought before the same society two specimens of general cystic disease of the liver—one from an infant of 7 weeks, the other from a stillborn child. Both specimens showed great increase in the fibrous tissue throughout the liver, especially in the portal spaces. Still believes this excess of fibrous tissue is due to persistence of the fœtal condition, in which a large amount of mesoblastic stroma is normal. This feature has also been described by other observers. Still collected 35 cases from the literature, and found the disease occurred three times as often in females as in males. Of the 35 cases, 3 only occurred in infants, while of 26 others in which the age is recorded 17 occurred in adults over 50. He also showed that there was no degeneration of the liver cells, and suggested a congenital origin for cystic disease of both liver and kidney. He believed the cysts were due to irregularity in development, some of the original columns of cylindrical cells being left with their original lumen.

Moschcowitz,[9] in 1906, was able to collect 85 cases from the literature, but found the disease affected the sexes about equally. By collecting the statistics of Lejars, Luzzato, and Johns, he found that 19 per cent. of cases of congenital cystic kidney were associated with a cystic condition of the liver. Moschcowitz himself investigated pathologically 5 cases of general cystic disease, and came to the following conclusions. 1. Non-parasitic cysts of the liver are always associated with other congenital defects in the body, especially cystic kidney. 2. They are always developed from aberrant bile-ducts. 3. These aberrant bile-ducts are embryonic rests, and are only found in cystic liver or in the liver of congenital cystic kidney. 4. Two forms of general cystic liver occur—one from inflammatory hyperplasia of the aberrant ducts, the process advancing centrifugally; the other caused by retention in these ducts, due to congenital obstruction. 5. Congenital cystic disease of the liver is not to be regarded as a tumour formation.

Shaw and Elting[10] added three more to the cases collected by Moschcowitz, and of the total number of 88 cases found that 2 were fœtal, 7 in newly born children, 4 occurred in the first year and 1 in the eleventh year. The other 74 cases occurred in adults, mostly in people over 60. All the cases in infants were multiple, and all were associated with other defects. Heredity was shown to play some part The following is a brief summary of other theories which have been brought forward [illegible]

1. That the cysts ar [illegible] (Pye-Smith[11]) It is [illegible] the production of a space bounded by a definite fibrous wall lined by nucleated cells.

2. Förster's[12] theory supposes that the cysts are due to dilatation of normal bile-ducts, which have been occluded by

inflammatory connective tissue. This theory received general acceptance at one time, and also received support in 1904 in a paper by Blackburn.[13] In many cases, however, there is no excess of connective tissue, and bile is usually absent from the cyst contents. Moreover, jaundice is never present in this condition.

3. Sabourin's[14] theory states that the condition is due to an overgrowth of bile-ducts, which he terms "biliary angioma."

4. That the cysts are tumours—in fact, cysto-adenomata, of the bile-ducts (Siegmund[15] and von Hippel[16]).

5. That the cysts are formed by tumour formation from embryonic remains (Borst[17] and Ribbert[18]).

Theories which invoke neoplastic formation as an explanation of the cysts are open to the very grave criticism that the microscopic appearance in early cases is unlike that produced by simple tumour formation elsewhere, the general appearance being one of infiltration rather than encapsulation. These theories are all discussed by Rolleston in his work on "Diseases of the Liver."

The condition of general cystic disease is, of course, not amenable to treatment, and is more of pathological than of clinical interest. In some cases, however, the largest of the cysts have been dealt with surgically, under the impression that a solitary cyst was present (*vide postea*).

Solitary Cysts.

Solitary cysts of the liver, on the other hand, are of considerable clinical interest, as they often produce well-marked symptoms and are usually amenable to surgical treatment.

Although the term "solitary cyst" is a convenient one, it will be found that in many cases of apparently solitary cyst the liver tissue adjacent to the cyst wall contains potential cysts in the shape of acini lined by epithelium, and in some cases actually small cysts in addition. The former resemble the aberrant bile-ducts which have already been described in association with general cystic disease. In fact, all stages seem to occur from a single cyst to general cystic disease, and the epithelial lining in all cases is practically always the same.

Solitary cysts may occur in children, but most of the reported cases have occurred in adults. When situated near the free margin or under-surface of the liver they often become more or less pedunculated, but sometimes they are entirely intrahepatic, with no suggestion of a pedicle.

As regards the pathology of solitary non-parasitic cysts, opinions are almost as diverse as in the case of general cystic disease. Comparatively few post-mortem specimens have been described. In 1882 Sharkey[19] brought before the Pathological Society a specimen of a solitary hepatic cyst from an adult patient who had died from cerebellar hæmorrhage. The cavity was of the size of a full-term fœtal head, and was entirely intrahepatic. Microscopically, the cyst was found to be lined by a single layer of flat epithelium, with an outer layer of fibrous tissue. The fluid contained no bile, but a large amount of albumin and chlorides.

Plenk[20] described the case of a woman, aged 40, who was admitted to hospital suffering from attacks of abdominal pain, swelling of the abdomen, and intermittent jaundice. The liver extended from the right fourth costal cartilage in the nipple line to the level of the navel. A clinical diagnosis of cirrhosis was made. Symptoms of peritonitis supervened, and the patient died shortly after a laparotomy. At the necropsy the peritonitis was found to be due to a perforated gastric ulcer. On the under-surface of the right lobe of the liver was a large smooth-walled cyst, reddish-white in colour, with patches of hæmorrhage, probably due to the coexisting peritonitis. Microscopically the cyst wall showed a layer of connective tissue lined by cubical epithelium, with isolated goblet cells. The liver tissue in close proximity to the cyst showed here and there proliferated bile-ducts. There were also large vessels showing proliferation of the intima, and islands of liver cells and some groups of leucocytes.

Shaw and Elting[21] relate the case of a single cyst of the liver treated by operation. The cyst had its origin in the right lobe and projected below the costal margin to the right iliac fossa. 900 c.c. of clear yellow fluid were drawn off, which contained a moderate amount of albumin. Microscopically only detritus was found. The patient died, and at the necropsy the cyst was found to be lined by a smooth glistening membrane, which on microscopic examination showed only fibrous tissue, no epithelium. The kidneys were normal.

Zahn[22] collected the post-mortem records of 14 cases. All had a ciliated columnar-celled lining, and in many cases smaller cysts lined by cylindrical epithelium were also present. The contents in all these cases were colourless, clear or slightly turbid fluid, yellow in only one case.

Bland-Sutton[23] gives an illustration of a solitary cyst growing from the free border of the liver. The specimen is in the Museum of the Royal College of Surgeons of England, and was obtained from a woman aged 38. Microscopically the wall consists of fibrous tissue lined by flat epithelium.

A considerable number of cases have been reported in which the cyst has been resected by operation, and the cyst wall and adjacent liver tissue subjected to microscopic examination. Hofmann[24] published such a case in 1902, and collected from the literature 17 other cases of solitary cyst in which operation had been performed. In some of these only incision and drainage had been done, while of those which had been resected a microscopic report is published only in 7. In Hofmann's case the wall of the large cyst showed no epithelial lining, but smaller cysts were also present with papillary growths projecting into their lumen. He regarded it as a cysto-adenoma of the bile-ducts. In König's[25] case, besides the large cyst, smaller cysts were also present, lined by cylindrical epithelium, and the same description also applies to Müller's[26] case. In Bayer's[27] case the cyst appeared to occupy almost the whole liver; incision and drainage were performed and a piece of the wall was removed for microscopic examination. This showed dilated bile-ducts and atrophied liver tissue. Müller's[28] second case is described as a cysto-adenoma. A large wedge of liver, including the chief cyst, was excised. The patient died, and at the necropsy many other large and small cysts were found in the liver. It is significant that in this case the kidneys also were cystic.

In Roberts's[29] case a very large cyst as well as a small one were opened and drained; the tumour is described as a papillary cysto-adenoma, and although not definitely proved, the case was thought to be similar to one operated upon by Keen in 1892, in which the cystic condition was shown to be due to the presence of coccidia. In Bobrow's[30] case multiple cyst formation was found in the wall of the large cyst, each cyst being lined by epithelium. Schultze's[31] case was a large solitary cyst lined by columnar epithelium.

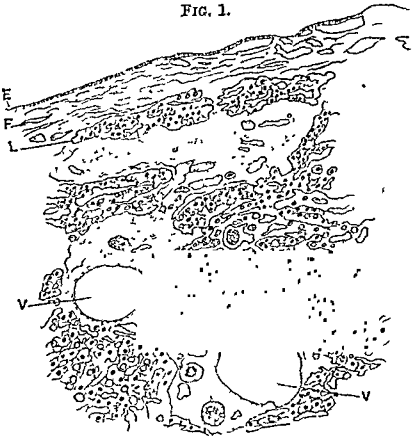
Bland-Sutton[32] resected a more or less pedunculated cyst, which showed at its junction with the liver small loculi lined by epithelium and biliary ducts lined by cubical cells. The large cyst itself was lined by flat epithelium. Bland-Sutton thinks that the cyst arose from dilatation and fusion of the bile-ducts, and suggests that the condition is possibly brought about by the pressure of stays on the thin anterior strip of liver.

Many German authorities regard cysts of the liver as an outgrowth from the bile passages of an adenomatous type. Ziegler[33] refers to the subject but briefly, stating that adenoma of the bile-ducts may be solid or cystic. His illustrations of this condition show a large number of acini in the peri-portal tissue without any very definite capsule. Von Haberer[34] also regards simple cysts of the liver as an adenomatous growth, and believes general cystic disease is a further and more advanced form of solitary cyst. His own case showed one large cyst and some smaller ones at the upper and lower poles, which communicated with the main cyst. Microscopically the cyst showed a lining of cubical epithelium, and the piece of liver excised with the cysts showed proliferation of the bile-ducts, apparently unlimited, however, by any definite capsule. Ikonokoff's[35] case is simply described as a cystic adenoma of the bile-ducts.

It will be noted from the foregoing abstracts that in many of the cases, besides the chief cyst, smaller cysts were also present, and on microscopic examination small loculi lined by epithelium and an unusual number of bile-ducts in the liver tissue adjacent to the cyst. In fact, as already stated, all stages seem to occur from a single cyst to multiple cystic disease. If the latter is believed to arise from aberrant bile-ducts, the so-called solitary cyst quite possibly has its origin in the same source. It will be noted in the following table that in one case of localised cystic disease the kidneys were also cystic—a condition which, as has been stated above, is frequently present with general cystic disease of the liver. This view of the origin of simple cysts is also supported by Kilvington,[36] who says that no sharp distinction can be drawn between large and small, single and multiple, cysts, and suggests that both have a similar origin.

The question of the contents of the cysts may, perhaps, be thought to throw some light on the matter. In general cystic disease the contents are usually clear watery fluid, sometimes yellowish-brown in colour. The fluid contains albumin, mucin, cholesterin, epithelium, and, rarely, bile. The contents of the solitary cysts are similar, except that bile is rather more frequently present. This is easily explained by supposing that, as the cyst increases in size, large intrahepatic bile-ducts come to open into it, their [illegible] essure atrophy. This would also [illegible] bile, which is reported in some [illegible] after the cyst has been opened and drained. Waring [illegible] states that bile may find its way *in this manner into a hydatid cyst, so the same process* may quite conceivably take place in a simple cyst. If the cysts arise as an adenomatous condition from normal bile-ducts, one would expect to find bile present in the fluid much more frequently than is actually the case. The presence of papillomatous growths in some of the cysts suggests more strongly a tumour formation, and possibly these cases may be of that nature, taking origin from aberrant bile-ducts. It will be noted, however, that Keen's case of cysto-papillo-adenoma of the bile-ducts was shown to be due to the presence of coccidia.

FIG. 1.



Section [illegible] dissecting room sub- ject [illegible] ls. F, Fib[illegible] s. V, Vei[illegible]

Some of the cases reported seem to have been retention cysts. Thus in North's[38] case, after several attacks of colic extending over four years with intermittent jaundice, a rapidly increasing tumour appeared in the left lobe of the liver. The cyst was aspirated, and five pints of coffee-coloured fluid was drawn off. The patient died from leakage of bile into the peritoneal cavity. At the autopsy the cyst was found to be the size of a man's head. There was a large calculus in the gall-bladder, and another the size of a marble in the common duct, one inch from the lower end. Waring[39] takes this view of North's case, but Hofmann[40] thinks it was a case of cysto-adenoma, and independent of the calculus in the duct.

In Mayo Robson's[41] case there was enlargement of the liver with jaundice. A cyst developed in the right lobe, which was aspirated, and 6 ounces of straw-coloured fluid drawn off. Two months later the cavity was opened with the cautery, and 8 ounces of fluid drawn off. Bile discharged freely from the wound. A month later Robson removed two stones from the common duct, and a large one from the gall-bladder.

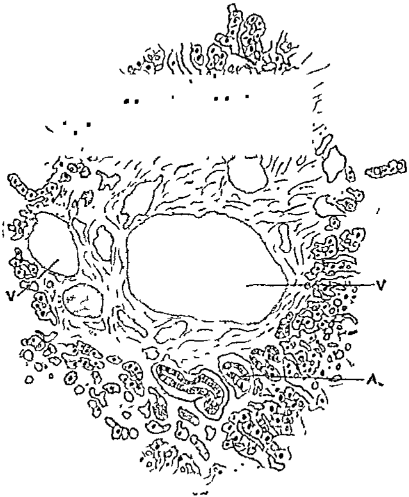
Another case of what was probably a retention cyst was published by Terillon.[42] In this case two litres of biliary fluid were drawn off by puncture. The patient died three months later, and post mortem a carcinoma of the liver was found and cystic dilatation of the bile-ducts.

Peyton Beale[43] has also recorded a case in which cystic dilatation of the liver was found post mortem two years after calculi had been removed from the gall-bladder and common duct. The cysts contained bile. Paton[44] has also recorded a somewhat similar case in which obstruction to the bile-ducts was caused by a hydatid cyst at the portal fissure. The intrahepatic cysts were caused by dilatation of the bile-ducts, and many of them contained calculi.

Retention cysts due to congenital atresia of the common bile duct have also been described. Witzel[45] describes a case of congenital atresia of the common bile-duct in a female non-viable child, with a large cyst in the left lobe and a smaller one in the right lobe which communicated with each other.

Retention cysts due to extreme dilatation of the extra-hepatic ducts from congenital atresia have also been recorded. Oxley's[46] case was a *female child of* 5 months, which had an enormously distended abdomen, was jaundiced and emaciated. An abdominal tumour had been noticed since birth, which *increased in size* and formed a rounded tense globular swelling. This was aspirated twice, 36 and 16 ounces of bile being drawn off. The child died, and at the autopsy the gall bladder was found to be normal but contained no bile. The cystic and hepatic ducts opened into the cyst, *which proved to be a dilated common bile duct.* The opening of this duct into the duodenum was impervious. Edgeworth's[47] case was a female child of 4½ years. Her illness began at the age of 6 months with an attack of jaundice which lasted three weeks. A tumour gradually developed, and was opened and drained. The child died, and post mortem it was discovered that the tumour was not, as was believed at th[illegible] ladder, but a greatly distende[illegible] end of the duct was very [illegible] only a hair-pin.

FIG. 2.



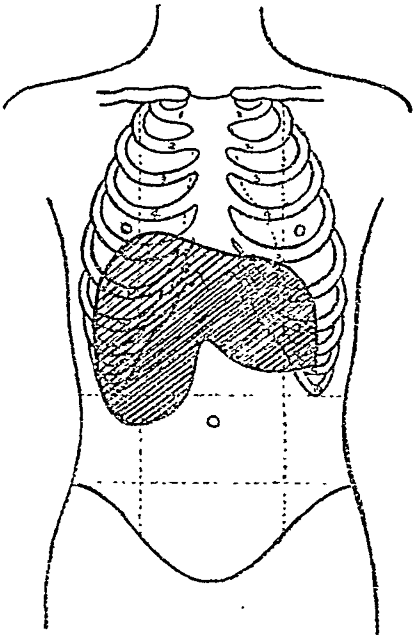
Section of another piece of the same liver, close to the portal fissure, apparently unaffected by cystic change. A, Aberrant bile-ducts. V, Vein.

Doran[48] has recorded a case of a woman aged 42, in which he believed that the cyst, which contained three pints of "pure bile," was traumatic in origin. Three years before coming under treatment she received a severe blow on the right hypochondrium from a fall against a wash-tub. The patient was three months pregnant at the time, and abortion followed in a few days. Doran suggests that the blow might have caused rupture of an intrahepatic duct, followed by slow extravasation of bile into bruised liver substance around it. As the cyst was opened and drained no portion was removed for microscopic examination. Kilvington thinks that cysts may also rarely develop from angiomata of the liver, while dilated lymph spaces have also been described as a cause of cyst formation. Langenbuch[40] mentions a case of dermoid cyst which contained hair and cartilage.

The following is a case of non-parasitic cyst which came under my own care :—

The patient, aged 27, first came under the care of my colleague, Dr. Basil Price, in October, 19[illegible] otes were made: "Married three years; one ch[illegible] in October, 1909. No miscarriages. She had [illegible]. No history of alcoholism or of any injury in the hepatic region. She nursed the child for five months and was treated for anæmia at the end of this time. Amenorrhœa since the birth of the child. Has had troublesome diarrhœa since July, 1909, the bowels acting several times a day; motions loose; never any blood. Occasionally she is constipated. Has complained of occasional pain in the right hypochondrium and epigastrium. No vomiting. Never had jaundice. Has wasted somewhat in the last 12 months. Is troubled with attacks of profuse sweating, especially at night." [illegible] conjunctivæ have yellowish tinge. Heart and lungs normal. No ascites or swelling of the feet. Liver greatly enlarged; lower edge of right lobe reaches to level of navel. (Fig. 3.) Left lobe also apparently enlarged, its lower edge being just above the subcostal plane; well-marked notch between the two lobes. Upper margin of liver dulness in right nipple line at fourth intercostal space. The surface was everywhere smooth and regular. Rectal examination negative. Blood count: Red cells, 5,200,000; white cells, 12,000; hæmoglobin, 80 per cent. Nothing abnormal in shape of red cells. Von Pirquet's reaction positive. Temperature subnormal in the morning, with usually an evening rise to 99° or 100°F.

FIG. 3.



Oct. 18th 1910

The patient stayed in hospital four weeks and gained 4 lb. in weight. The bowels acted from two to five times a day. She was able to eat ordinary food.

The patient was readmitted to the hospital on Oct. 9th, 1911, under my care, Dr. Price having seen her as an out-patient some days previously. Since leaving the hospital a year ago she has had occasional pain over the liver; there has been no swelling of the feet. Has had some shortness of breath.

Condition on Oct. 9th, 1911.—Weight, 7 st. 11½ lb. No trace of jaundice. Blood count: red cells, 4,940,000; white cells, 15,000. Abdomen: Liver greatly enlarged, with an obvious rounded projection forwards below the inner part [illegible] (Fig. 4.) On palpation this projection was f[illegible] in it was not great. The lower edge of [illegible] umbilical plane. Peritoneal friction was palpable and audible through the stethoscope over the cyst. The rest of the liver was firm. Liver dulness began above in the right nipple line at the second intercostal space and was absolute at the fourth space. No hydatid fremitus made out. The left superficial epigastric vein was very much dilated and tortuous; the blood-flow in this vein was definitely upwards. Right vein not noticeable. Veins also visible over lower part of chest.

[illegible] f the right lobe of the liver, possibly hydatid or [illegible] cyst. The chief point against hydatid was the [illegible] ision in the cyst. There was no eosinophilia. [illegible] ught to be due to pressure upon the portal vein causing portal congestion, and thus to correspond to the diarrhœa of alcoholic cirrhosis. The dilated superficial epigastric vein was thought to be due to pressure upon the inferior vena cava, although its presence only on one side was a curious point. The cyst has obviously enlarged considerably in the last 12 months, mainly in an upward and forward direction.

Operation.—A three-inch incision was made over the most prominent part of the cystic swelling, just below the costal margin, through the fibres of the right rectus. A few delicate adhesions were found between the tumour and the anterior abdominal wall. At the most prominent part the wall of the cyst was milky-white in colour, from thickening of the peritoneal coat; outside this area the colour was a greenish-brown. The abdomen was packed off with gauze and an exploring needle and syringe drew off from the cyst a green fluid looking like bile. The cyst was then emptied with a trocar and cannula, four pints of the same kind of fluid being drawn off. A probe passed into the cyst for a distance of 7 inches and revealed an enormous cavity which must have extended almost to the diaphragm above and crossed the middle line for several inches. It was not considered advisa[illegible] wall, and microscopic examination of the [illegible] as made would probably not have reveal[illegible] wall at this point was thin and fibrous. A rubber tube was fixed in the opening into the cyst, which was stitched to the parietal peritoneum. The rest of the wound was closed in layers in the usual way. The gall-bladder and bile-ducts were not seen, but the cyst was clearly intrahepatic and quite independent of these structures.

After-history.—For some days after the operation there was a profuse discharge of bile-coloured fluid, which changed from green to a yellow-green, and also became thicker and more mucoid than that removed at the operation. The cavity was washed out with sterile water. The diarrhœa ceased immediately after the operation and did not return. The day after it was noted that the direction of the blood flow in the left epigastric vein was distinctly downward, whereas before the operation it had been distinctly upward. I take this to mean that the pressure on the portal vein and the inferior vena cava had been relieved by emptying the cyst. On Oct. 21st it was noted that the upper margin of liver dulness in the right nipple line was now at the sixth rib, and the lower edge of the liver could be felt an inch above the level of the navel. The night sweats continued as before the operation. Some infection of the cavity occurred a week or so after the operation, the discharge became offensive and muco-purulent, and the temperature rose every evening to about 100°-101° F. This subsided after a few weeks, and by the end of December the capacity of the cavity had diminished to 5 oz.

On Jan. 11th a most unfortunate incident occurred. The cavity was being irrigated with a weak solution of hydrogen peroxide, a proceeding which had been performed by the ward sister daily for some weeks with beneficial results, when the patient complained of severe pain. [illegible] occurred from the sinus. The opening had [illegible] considerably, and the tube fitted closely. Apparently the pressure caused by the escaping gas from the hydrogen peroxide either ruptured the cavity or tore it from the abdominal wall. Peritonitis rapidly followed, and laparotomy was performed. Bile-stained purulent fluid was found all over the abdomen; the pelvis and both loins were drained, but the patient died next day. This unfortunate occurrence shows the danger of using peroxide of hydrogen for the irrigation of cavities unless there is very free exit for the evolved gas, a danger to which, as far as I know, attention has not previously been called. The accident occurred three months after the operation, and there is every reason to believe that, but for its occurrence, the patient would have made a complete recovery. No post-mortem examination was allowed.

Examination of the fluid contents of the cyst.—Clear, slightly mucoid, dark green in colour, specific gravity 1007, slightly alkaline, albumin present in abundance. Bile tests (Pettenkofer and Gmelin) strongly positive. No reduction with Fehling's solution. Slight deposit on standing, which microscopically consists of granular débris, cholesterin crystals in abundance (notched plates), no hooklets or scolices.

This is undoubtedly one of those rare cases of hepatic (presumably solitary) cysts of non-parasitic origin. Its position in the interior of the right lobe of the liver excludes the possibility of its having arisen from dilatation of the gall-bladder or of the extra-hepatic bile-ducts. Moreover, obstruction to the cystic duct, as, for instance, by an impacted calculus, produces a hydrops of the gall-bladder, the contents of which are almost clear mucus, whereas the contents of this cyst were almost pure bile. The absence of jaundice, with the exception of a faint tinge noticed a year before the operation, practically excludes obstruction in the extrahepatic ducts as a cause of the cyst formation. It is known that calculi may exist for a long time in the common duct without giving rise to jaundice, but in these cases there cannot be any increase in pressure in

Oct. 9th 1911. X Fluctuation.

Table giving Details of 54 Cases of Large Cyst or Cystic Tumour of the Liver submitted to Operation

No	Operator, year, and publication	Sex and age	Symptoms, &c	Site	Contents	Operation	Pathological report	Result
1	Gloz 1864 (cited by Winckler, Zur Kasuistik der Leber cyst Inaugural Dissertation Marburg 1891)	M, 28	Large cyst, rapid growth, caused severe dyspnœa	Right lobe anterior and inferior surfaces	6 litres removed in two tappings	Multiple punctures	Not described	Death after several punctures
2	Cousins, 1874 Brit Med Jour, 1874, vol ii, p 700	F 27	Diagnosed as ovarian Large cyst.	Under surface	2½ gallons clear limpid yellow fluid	Partial resection Stump fixed to abdominal wall	Simple cyst Specimen in Royal College of Surgeons Museum	Death 36 hours after operation from peritonitis
3	North 1882 New York Medical Reports, 1882	M 45	Attacks of colic and jaundice due to calculi in common duct Rapidly increasing swelling below left costal margin	Left lobe	5 pints coffee coloured fluid Specific gravity 1015 Contained albumin and bile	Aspirated	Cyst size of man s head	Death from leakage of bile into peritoneal cavity Post mortem, calculi in gall bladder and common duct
4	Kaltenbach (cited by Winckler, cf No 1)	F	Diagnosed as ovarian 10 years history Filled whole abdomen Punctured several times (320 litres in all drawn off)	Inferior surface	Viscid greenish brown fluid	Resection	Not described	Recovered Well 5 years later
5	König, 1886 (cited by Hüter, Inaugural Dissertation, Göttingen, 1887)	F, 11	Filled whole abdomen Rapid development Fluctuation	Inferior surface of right lobe	2½ litres greyish fluid containing cholesterin	Resection Raw surface closed by suture	Large and small cysts, lined by cylindrical epithelium (Diagnosis cysto-adenoma)	Recovery
6	Ahlfeld 1890 (cited by Winckler, cf No 1)	F 38	Diagnosed as ovarian Irregular painful menstruation	Inferior surface	8 litres slimy yellow fluid Albumin trace of bile, cholesterin	Incision and drainage	Cyst wall of connective tissue No epithelium demonstrated	Recovery Fistula at end of 3 months
7	Muller 1891 Verhandlungen der deutschen Gesellschaft für Chirurgie, 1893	F, 59	Filled whole abdomen Swelling noticed 10 years ago Bladder symptoms diagnosed as ovarian	"	6 litres chocolate coloured fluid	Resection of two thirds suture of rest to abdominal wall	Large and small cysts lined by epithelium Diagnosis: cysto adenoma	Recovery Well after 6 years (Verhandlungen der deutschen Gesellschaft für Chirurgie, 1897 1 137
8	Terillon, 1891, Bulletin et Mémoires de la Societe de Chirurgie, 1891	M, 52	Great wasting Intense jaundice	Intra hepatic	2 litres bilious fluid	Puncture	Probably a retention cyst	Death after 3 months Post mortem carcinoma of liver and cystic dilatation of bile-ducts
9	Körte (cited by Langenbuch)	?	Cysts as large as an egg	Liver margin	Serous fluid	Incision and drainage	Not described	Recovered
10	Bayer, 1892 Prager Medicinische Wochenschrift 1892, No 52	F, 56	*Very large tumour Rapid development (4 months)* Fluctuation Bowels irregular No jaundice Pallor	*Occupied* whole liver	*8 litres* brownish grey fluid	"	Section showed atrophied liver tissue and dilated ducts	Recovered.
11	Berg 1894 Hygieia, Band iv, 1894	F 45	Epigastric tumour, size of hen s egg, to left of mid line	Anterior border of left lobe Pedunculated	—	Resection	—	Recovery
12	Roberts 1894 American Journal of Medical Sciences 1894	F 56	Great enlargement of liver	Intra hepatic	Clear limpid fluid	Operation in two stages Cyst incised on eighth day Also several small cysts opened	Diagnosis cysto adenoma	Died 3 weeks *after operation* Bed sores Post mortem, liver greatly enlarged Over three-fourths of it riddled with cysts One contained pus Both kidneys cystic
13	Chrobak 1894 Wiener Klinische Wochenschrift, 1898 No 14	F, 46	Swelling in region of liver 5 years No pain Last six months pain, dyspnœa, loss of strength Filled almost whole abdomen Surface bossy Fluctuation	Large cyst in right lobe	Half a litre fluid Yellow green alkaline No bile No sugar Albumin 30 per cent, specific gravity 1014	Operation in two stages Incision and drainage	Smaller cysts scattered over surface of liver, chiefly in right lobe	Recovered Well 5 months later
14	Muller, 1896 Verhandlungen der deutschen Gesellschaft für Chirurgie 1897, I, 137	F	Very large reached to pelvis 6 years history	Right lobe	Clear serous fluid	Excision of a large wedge Innumerable small cysts opened in the process	Diagnosis cysto adenoma Cysts varied in *size from a pea to a fist*	Died on eleventh day *from* embolism Post mortem, kidneys also cystic
15	Czerny, 1898 (cited by Petersen, Verhandlungen der deutschen Gesellschaft fur Chirurgie, 1898)	?	Large tumour.	?	?	Resection	Cyst of bile-ducts	Recovered
16	Bobrow, 1898 Chirurgia Band iv p 36 Reference in Centralblatt fur Chirurgie 1899 No 10	F, 51	Swelling 4 years At first size of a fist, finally 20 ins in diameter Connected with liver Gall bladder lay behind	Inferior surface	*Dark fluid* containing threads	*Resection of* sac stump sutured to abdominal wall	*Multiple cyst formation* in wall lined by epithelium Diagnosis: adeno-cystoma	Recovered

Table giving Details of 34 Cases of Large Cyst or Cystic Tumour of the Liver submitted to Operation (continued).

No.	Operator, year, and publication.	Sex and age.	Symptoms, &c.	Site.	Contents.	Operation.	Pathological report.	Result.
17	Porter, 1898 (reported by Shattuck). Boston Medical and Surgical Journal, 1900, p. 427.	F., 63	Abdominal swelling; painless; not tender; reached to iliac crest. Fluctuation. Hæmorrhage from bowel.	Upper surface of liver, close to falciform ligament. Liver pushed down.	1 gallon of clear, colourless fluid. After a time some bile discharged from sinus.	Incision and drainage.	Diagnosis: cysto-adenoma of bile-ducts. Cyst wall contained bile-ducts and small cysts.	Died some months later after second operation to close persistent sinus.
18	Schultze (cited by Leppmann). Deutsche Zeitschrift fur Chirurgie, Band liv., 1900.	F., 14	Swelling 14 days. No jaundice. Round tumour [illegible] tion.	Inferior surface.	1500 c.c. Viscid turbid yellow-brown. Specific gravity 1013. No sugar.	Resection of sac; operation in two stages.	Cyst lined by columnar epithelium. Dilated bile-ducts in outer layer of cyst.	Recovered, with persistent sinus.
19	C. Hofmann, 1900. Mittheilungen aus den Grenzgebieten der Medizin und Chirurgie, 1902.	F., 28	Abdominal swelling 6 months. No trauma. Tumour occupied almost whole abdomen, especially above, to right.	Pedicle attached to quadrate lobe.	Muddy; yellow-grey. Albumin. Cell detritus.	Resection; raw surface sutured.	No epithelium in large cyst. In wall were smaller cysts with papillary growths projecting into lumen.	Recovery.
20	Schmidt (cited by Waring).	F., 60	Small tumour of liver.	?	?	Resection.	Reported as cysto-adenoma. Tumour contained a mass of cysts.	Recovery. Well 6 years later.
21	Bird (reported by Kilvington). Intercolonial Medical Journal of Australasia, vol. vii., 1902, p. 557.	?	Fluctuation. Low-tension cyst.	?	?	Incision and drainage.	Simple cyst.	Recovered. Two years later cyst refilled, or a fresh one developed.
22	Mayo Robson, "Gall-stones," Case 28. (Also "Diseases of Gall-bladder," Case 35.)	F., 42	[illegible] lated; opened again. Jaundice improved at first; then stationary.	Right lobe.	6 oz. clear straw-coloured. Later 8 oz. Bile discharged from wound later.	Aspirated first; then incised with cautery. Cholecystotomy and choledochotomy 4 weeks later.	? Retention cyst.	Died from pneumonia several weeks later.
23	Doran, 1903. Transactions of the Royal Medical and Chirurgical Society, 1904. Also Brit. Med. Jour., 1903, vol. ii.	F., 42	Blow over liver 3 years previously. Jaundice 4 *months*. Irregular vomiting. Profuse perspiration. Liver enlarged. 10 days before admission violent attacks of pain in upper abdomen. Attacks recurred. Diarrhœa. Large fluctuating swelling to right of navel. Menstruation regular but scanty. Wasting.	Right lobe. Gall-bladder and ducts lay behind.	48 oz. pure deep green bile. Later 16 oz. bile removed. Free discharge of bile from wound for some weeks.	Incision and drainage.	? Traumatic cyst.	Recovery. Cyst closed in 9 months. Patient well 6 months later. (Brit. Med. Jour., 1905, vol. ii., p. 1319.)
24	Miller, 1903. American Journal of Obstetrics, vol. xlviii., August, 1903, p. 182.	F., 2½	Abdomen enlarged at birth. No jaundice.	Reported by Doran as intrahepatic. Miller believed it to be a dilated gall-bladder.	5 pints of bile.	Operation in two stages. Opened with cautery.	—	Recovery.
25	Morton, 1903. THE LANCET, Nov. 14th, 1903, p. 1395.	F., 63	Swelling 2 months. No other symptoms. Cyst size of an orange.	Right lobe just above quadrate lobe.	Clear, straw-coloured fluid.	Incision and drainage.	Simple cyst.	Recovery.
26	Blackburn, 1904. Transactions of the Pathological Society, vol. lv.	F., 49	Swelling under left ribs for several months. Albumin and pus in urine.	Right lobe. Cyst size of tennis ball.	Watery straw-coloured fluid; no sugar. Albumin.	Incision and aspiration.	Large number of smaller cysts present.	Recovery. Left kidney excised later; it was a mass of cysts. Well 3 years later.
27	Reid. Intercolonial Medical Journal, vol. i. (Cited by Blackburn.)	M., 62	Pain in left lobe of liver. Swelling.	—	Bile-stained fluid.	Incision and drainage.	—	Died. Post mortem, cystic kidneys, and liver honeycombed with cysts.
28	Bland-Sutton, 1905. Brit. Med. Jour., 1905, vol. ii., p. 1167.	F., 75	Epigastric swelling, size of apple, increased to size of man's head. Painless. Clinically resembled mesenteric cyst.	Lower border of left lobe. Pedunculated.	2 pints brown fluid, neutral. Specific gravity 1007. Trace of blood; no sugar. Scanty solid matter.	Resected.	Wall consisted of fibrous tissue lined by flat epithelium. At juncture with liver, several small loculi lined by epithelium, and several biliary ducts. (Lockyer.)	Recovery.
29	Ikonokoff, 1906 (Russk. Vrach, St. Petersburg, 1906. Quoted *in extenso* by von Haberer. *Vide* No. 30).	?	Jaundice 15 years previously. Pain in region of liver; swelling.	In right lobe.	?	Partial resection; stump fixed to abdominal wall.	Cyst size of child's head. Diagnosis: cystic adenoma of bile-ducts.	Recovered. Still had fistula 1½ years later.

Table giving Details of 34 Cases of Large Cyst or Cystic Tumour of the Liver submitted to Operation (continued)

No	Operator, year, and publication	Sex and age	Symptoms, &c	Site.	Contents	Operation	Pathological report	Result
30	Von Haberer, 1909 Wiener Klinische Wochenschrift, 1909 vol xxii, p 1788	F, 34	Six months pain in upper abdomen Vomiting of watery fluid Night sweats Swelling : 14 days Size of child s head in epigastrium Gastric *peristalsis visible to left* of cyst Colon below tumour Diagnosed as pancreatic cyst or adhesive form of tuberculous peritonitis	Occupied whole of left lobe extending right up to falciform ligament	Clear bright yellow mucin Albumin 6 per cent Bile pigment Glycogen	Left lobe excised *in toto*	One large cyst, several smaller ones at upper and lower poles which communicated with large cyst Lined by cubical epithelium Adjacent liver *show* excessive number of bile ducts Diagnosis : cysto adenoma of bile-ducts	Recovery.
31	Shaw and Elting, 1909 Archives of Pediatrics New York 1909 vol xxvi, p 818	F, 1½	Abdominal swelling increasing Projected below costal margin to right iliac fossa and to mid line No jaundice	Right lobe	900 c c clear yellow fluid Moderate amount albumin	Incision and drainage	Cyst lined by smooth glistening covering No epithelium could be seen	Died from shock Post-mortem kidneys healthy, gall bladder normal
32	Aldous 1911 Brit Med Jour, 1911, vol i	F 43	Epigastric swelling 2 months Biliousness No pain Fluctuation	"Free border of liver	12 pints thin, dark, muddy fluid No bile Hæmoglobin crystals	Incision and drainage	Simple cyst	Recovery.
33	Corner 1912 Medical Press and Circular, 1912	F	15 years, attacks of colicky pain in right hypochondrium Vomiting No jaundice Tumour suggested distension of gall bladder	Right lobe Anterior margin Cyst 4 in in diameter	Slightly opalescent fluid	Resection	Simple cyst	Recovery.
34	Sidney Boyd, 1911	F 27	Anæmia, amenorrhœa, diarrhœa Pain in right hypochondrium No vomiting No jaundice Wasting Temperature 99° 100° F Profuse perspirations Some dyspnœa Fluctuation	Right lobe, intrahepatic	4 pints clear mucoid dark green Specific gravity 1007 Alkaline Albumin Bile present Cholesterin	Incision and drainage	Simple cyst	3 months after operation died from peritonitis following rupture of sinus

the bile ducts The presence of a large quantity of bile in a simple cyst, apart from those due to retention, is of rare occurrence With the exception of Doran's case which was believed to be due to trauma and in which the contents were also practically pure bile, this is the only case on record in which bile was present in any great quantity In the report of some cases, however, the presence or absence of bile is not stated The explanation of the presence of bile in a simple intrahepatic cyst has already been suggested—namely, that as the cyst enlarged, an intrahepatic duct or ducts came to open into it This would also account for the discharge of bile which occurred after the operation The absence of a post-mortem examination, of course, leaves one in some doubt, but I am inclined to regard this case as one of a simple cyst, probably arising in aberrant bile ducts

I have been able to collect 33 cases from the literature in which a large cyst or cystic tumour of the liver has been subjected to operative treatment Eighteen of these were collected by Hofmann[50] in 1902, and Doran[51] gave an abstract of five of these cases in his paper in 1903, together with three others not quoted by Hofmann As Doran's is the only paper published in English in which any number of cases has been collected, it seems advisable to give an abstract of all the reported cases in the accompanying table

Cysts may also occur on the surface of the liver under its peritoneal coat or in the peritoneal ligaments of the liver Thus Henderson[52] records a case of cyst of the round ligament of the liver operated on by Mayo The symptoms came on suddenly with violent epigastric pain, from which the patient recovered and had no discomfort for some time afterwards

A case recently came under my notice of a woman with advanced cystic disease of both kidneys She died while in hospital from uræmia, and at the necropsy, besides the polycystic condition of the kidneys there were two thin-walled serous cysts on the under surface of the liver, close to the portal fissure Possibly the case recorded by Ward Cousins (No 2 in the table) and also some others belongs to this category.

A similar case came under my observation in 1908 The patient was under the care of Mr Peter Daniel at Charing Cross Hospital, who operated upon her and who has kindly allowed me to refer to the case here She was a woman aged 56, who had suffered for over two years with pain after food and irregular vomiting A swelling had been detected in the region of the gall bladder two years previously and operation advised but declined The swelling had increased more rapidly in the last two months At the operation a large thin walled cyst was found to spring from the under-surface of th [illegible] ay on the left side of the cyst and [illegible] There were no calculi in the comm[illegible] cyst was extirpated and the gall bladder removed The contents of the cyst, which amounted to several pints, consisted of straw coloured fluid, specific gravity 1010, alkaline, contained a moderate amount of albumin, but no bile No epithelium could be demonstrated in the cyst wall Possibly these cases have an origin in an extrahepatic aberrant bile duct, which has been shown by Renault[53] to occur especially on the inferior surface

Clinical features of solitary non parasitic cysts of the liver —The most striking point is the great preponderance of the condition in the female sex Of the 34 cases collected in this paper 24 were in females, 4 are stated to have occurred in males, while the sex is not stated in 6—i e, out of 28 cases in which the sex is stated nearly 86 per cent were in females Of the 4 which occurred in males, one was North s case of retention cyst due to an impacted calculus; one was Terillon's case associated with carcinoma of the liver, and was also probably a retention cyst The greater preponderance of the condition in females is in agreement with its suggested congenital origin, as developmental defects are well known to be more common in that sex Both Hofmann[54] and Bland Sutton[55] think the greater frequency in females is possibly associated with the pressure of stays

The age of the patients is stated in 26 The youngest was Shaw and Elting s case, which was 18 months old Miller's case was operated on at the age of 3, but the abdomen had been noticed to be enlarged at birth The oldest was 75 (Bland Sutton's case)

The clinical signs and symptoms are very variable, depending on the size and situation of the tumour and its pressure effects

Pain does not appear to be a very marked feature Indeed, in some cases its entire absence is particularly stated A certain amount of pain in the upper abdomen is reported as occurring in some cases, in my own case this was associated with palpable friction over the cyst, due to localised peritonitis. Doran's case had several attacks of pain in the ten days preceding operation.

Dyspepsia and vomiting occurred in several cases. Gastric peristalsis was noted in one case. Diarrhœa was a marked feature in only two cases; this may have been due to portal congestion from pressure caused by the cyst. Irregular action of the bowels is noted in some cases.

Jaundice, independently of calculi in the common duct and malignant disease, occurred in only one case. It was apparently due to pressure on the bile-ducts at the portal fissure, but catarrh of the ducts may also have been a contributory cause. In my own case a faint trace of jaundice was noted about a year before operation, but soon passed off.

Interference with menstrual function is recorded in some cases, the catamenia being scanty or absent altogether. A certain amount of wasting and loss of strength was sometimes present, while profuse perspiration was a noticeable feature in two cases.

An abdominal swelling, in most cases diagnosed as a cyst, was present in all cases. Its size varied from a comparatively small tumour to one occupying almost the whole abdomen. In the latter cases dyspnœa was sometimes present, and in one case pressure on the bladder caused symptoms.

Fluctuation was generally readily obtained. In some cases the surface was bossy. A characteristic feature of non-parasitic cysts is their comparatively low tension. A connexion of the cyst with the liver can generally be made out by careful palpation, if necessary in a hot bath to secure good muscular relaxation. In the smaller cysts the tumour was situated in the upper part of the abdomen, usually on the right side, sometimes in the middle line or on the left. The cyst sometimes extends upwards and causes elevation of the diaphragm, raising the level of hepatic dulness. Rapid development of the cyst is often a striking feature. On the other hand, in some cases the cyst had been known to be present for many years before treatment was sought.

Enlarged superficial abdominal veins were not noted in any case except my own. This point and its explanation have already been referred to. Considerable hæmorrhage from the bowel occurred in one case, but hæmorrhoids were not specially stated to be present.

Probable course and complications.—Progressive increase in size, often at a rapid rate, is to be confidently expected in these cases. If neglected no doubt the patient will die in the same way as a case of ovarian cyst. Destruction of liver tissue in a large intrahepatic cyst will no doubt hasten the end.

I can find no account of the occurrence of spontaneous or traumatic rupture of a simple liver cyst, but it is of course a possibility. Torsion might conceivably occur in a very much pedunculated cyst, but, as a rule, the pedicle is too thick and short. Kilvington[56] refers to a case of fatal hæmorrhage into a non-parasitic liver cyst under the care of Allen, but otherwise there is no record of this accident. Kilvington observes, however, that minute hæmorrhages are frequent even in small cysts. Suppuration may quite conceivably occur, although no reference to it is made in the literature. Some cases of liver abscess may be suppurating cysts. Suppuration had occurred in one of the cases of general cystic disease reported by Moschcowitz.

Prognosis.—I think we may agree with Hofmann[57] that, if operable, the prognosis of non-parasitic cysts of the liver is not unfavourable. That of general cystic disease is, of course, very bad, especially if associated with cystic kidneys. It must be remembered, however, that in many of the cases reported in which a single cyst was believed to be present operation has disclosed the fact that multiple cysts, or even general cystic disease, sometimes with cystic disease of the kidneys, has been present. Moreover, fresh cysts may develop after one has been cured by operative measures, as in the case recorded by Bird.[58]

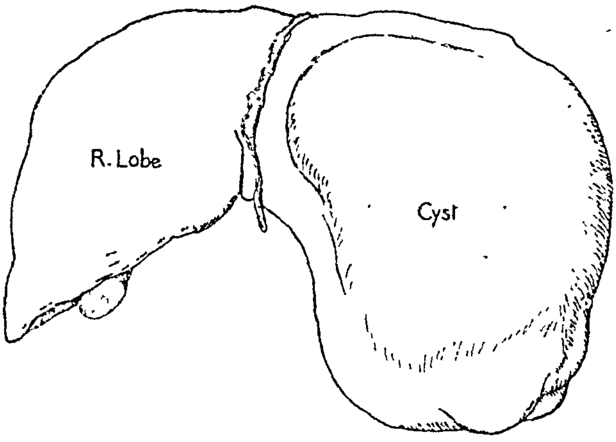
Treatment.—Operative treatment is indicated in all cases of apparently solitary cyst of the liver, and even when multiple cysts have been present considerable relief has been afforded by treatment of any large cyst or cysts. The exact procedure will depend upon the condition found on opening the abdomen. Bland-Sutton[59] urges that resection should be performed, and whenever possible this is the operation of choice. A wedge of liver at the base of the cyst is excised, and it may be possible to bring the surfaces together by suture. Where the cyst is at all pedunculated this is readily done, but when the cyst invades the substance of the liver to a large extent this would be a formidable proceeding, and in some cases impossible. No doubt individual surgeons would differ in their practice in border-line cases. An additional argument in favour of resection with the neighbouring hepatic tissue is that potential cysts would also be removed and recurrence of the trouble prevented.

Partial resection of the sac with suturing of the stump to the edges of the parietal incision has been done in several cases with satisfactory results. No doubt the smaller cavity so produced would close sooner than if the whole cyst were drained. This procedure, however, could only be done in certain cases, and when the cyst is almost entirely intrahepatic, incision and drainage is the only method to be adopted. The resulting cavity may take months to close. It is difficult to avoid infection in cases where prolonged drainage is carried out.

Kilvington[60] warns against the use of the curette, and no doubt the resulting hæmorrhage may be dangerous. The same writer suggests that a simple cyst should be dropped back into the abdomen when emptied, unless bile or calcareous plates are present. Presumably refilling of the cyst would be more likely to occur after this procedure than if drainage is adopted.

Simple puncture should not be performed. Although it has sometimes met with success it has often been fatal. Of the cases collected together in this paper, and in which surgical treatment was adopted, recovery occurred in 23.

FIG. 5.



Von Haberer's case of non-parasitic cyst of the left lobe of the liver. The whole of the left lobe was successfully resected.

Fig. 5 shows the condition of the liver in Von Haberer's case, in which the whole left lobe of the liver was successfully resected.

Postscript.—Since this paper was written a later edition of Dr. Rolleston's work on Diseases of the Liver has been published. In reference to Moschcowitz's view, to which reference has been made in this paper, Dr. Rolleston does not consider the structures described by him are aberrant bile-ducts, but the microscopic cysts of a cystic liver. Dr. Rolleston thinks that general cystic disease of the liver is quite possibly due to some special form of fœtal cholangitis and pericholangitis, causing obstruction to the bile-ducts. This practically coincides with Förster's theory, which has been referred to above.

New Cavendish-street W.

NOTES ON

THE PATHOLOGY OF TUBERCULOSIS IN INFANCY AND CHILDHOOD.

BY C. PAGET LAPAGE, M.D. VICT., M.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY;
AND
WILLIAM MAIR, M.D. EDIN.,
PATHOLOGIST TO THE HOSPITAL.

IN the post-mortem room the evidence as to the nature of tuberculosis in young children does not always agree with the views sometimes put forward. It is noticeable that the disease often affects the lymph nodes of the abdomen and thorax, and is in many instances limited to these nodes. Such disease may exist and not be suspected during life. However, there is danger of making too much of the lymph-gland disease and in that way of overlooking the fact that chronic pulmonary tuberculosis, with or without cavitation, is by no means rare in young children. An analysis of the post-mortem records made during the last six years at the Manchester Children's Hospital, Pendlebury, shows the nature of tuberculosis in children of the class admitted to hospital wards. Both medical and surgical cases are included. The cases are selected in the sense that they were thought suitable for in-patient treatment and that they died. Further, 76 per cent. of the cases showing tuberculous lesions at the post-mortem examination had actually died from the tuberculous affection, and in the remaining 24 per cent. the tuberculous lesion was either unimportant or was not the cause of the fatal illness. These facts are pointed out in order to show that the figures to be given later do not refer to tuberculosis in children in general.

General figures.—During a period of six years—March, 1906, to February, 1912—there were 962 deaths, of which 242, or 25 per cent., were clinically tuberculous, and 323 necropsies, of which 150, or 46 per cent., showed macroscopic evidence of tuberculosis. Of the 150 cases, 89 per cent. showed glandular tuberculosis, 17 per cent. showed glandular tuberculosis alone, 54 per cent. showed pulmonary tuberculosis, 14 per cent. pulmonary tuberculosis alone, 49 per cent. intestinal and peritoneal tuberculosis, 12 per cent. peritoneal tuberculosis with no intestinal disease, 3 per cent. tuberculosis limited to the intestine and abdominal glands, and at least 44 per cent. marked general tuberculosis. The evidence from the post-mortem examination can be conveniently divided into four main headings: (1) glandular tuberculosis; (2) pulmonary tuberculosis; (3) meningeal tuberculosis; and (4) tuberculous mediastino-pericarditis.

1. *Glandular tuberculosis.*—In only 16 of the 150 cases (11 per cent.) showing tuberculosis were the lymph nodes free from that disease. Probably this percentage would have been lower if the glands had been tested microscopically or by inoculation. The glands most commonly affected are the bronchial in the thorax and the mesenteric in the abdomen. In comparison the mediastinal and retro-peritoneal are rarely affected. The abdominal glands were more often affected than the thoracic, and it is curious that most other observers have found the reverse to be the case. Thus Rillet and Barthez made the ratio of thoracic to abdominal 79 to 46; Guthrie 54·5 to 24·6; Still 81 to 59; Shennan 62·9 to 48·7; whilst our ratio works out at 55 to 71. This is interesting because there is little doubt that abdominal tuberculosis is more common in some localities than in others. However, it is not justifiable to base any general conclusion on this fact without further evidence, because the cases were in-patients who may have been selected for admission since they were abdominal in nature.

Of the 107 cases showing tuberculosis of the abdominal glands: (1) 32 per cent. showed no intestinal disease; (2) 29 per cent. showed neither intestinal nor peritoneal disease; (3) 16 per cent. showed abdominal glandular affection with no other tuberculosis at all; (4) 48 per cent. showed both lung and intestinal disease; (5) 10 per cent showed lung disease with no intestinal ulceration; and (6) 10 per cent. showed intestinal disease without lung affection. In 30 per cent. of the 150 cases the disease seemed to have been primarily abdominal. In this connexion it must, however, be pointed out that infection by the digestive tract includes the swallowing of dirt, dust, and dried sputa, and is therefore not by any means limited to infection with the bovine type of bacillus nor to milk infection.

Of 83 cases showing tuberculosis of the thoracic glands 60 had also lung disease and 23 had none. Thus in 28 per cent. there was thoracic glandular tuberculosis without accompanying lung disease. In those cases in which the disease was limited to the thorax 18 showed lung tuberculosis and 4 none. Therefore in 4 cases there was tuberculosis of the thoracic glands and no evident tuberculosis elsewhere in the body.

In 26 of the 150 cases (17 per cent.) the glands were the only parts affected. In 17 the disease was confined to the abdominal glands; in 4 to the thoracic, and in 5 it affected both groups

The above figures show that disease of either group of glands may occur without lesion of the area drained by them. This occurred in 28 per cent. of the cases with thoracic glands, and 32 per cent. with abdominal glands affected. From the fact that in 28 per cent. of the cases with thoracic glandular disease and 32 per cent. of those with abdominal glandular disease there was no affection of the areas drained by those glands, it appears probable that the disease may spread from the abdominal to the thoracic glands and *vice versâ*. It must be pointed out, however, that tubercle bacilli may pass through a healthy or a slightly damaged mucous membrane without leaving any trace of their entry and yet infect the lymph nodes. Also we must not overlook the spread of tuberculosis by the blood stream in children, in whom generalised tuberculosis is so common.

2. *Pulmonary tuberculosis.*—In many of the cases with cavitation even in those under two years of age the cavities were at the apex, were definitely of a chronic nature, and had evidently been present before other and more wide-spread disease that was often evident. The subjoined table shows that 3 of the infants under two years, and in all 11 of the children had apical cavities.

Chronic Pulmonary Tuberculosis.

(a) With cavitation.

Site.	Age-period. 0–2	2–5	5–10	10–14	Total.
Apex	3	2	2	4	11
Upper lobe	—	3	2	1	6
Middle ,,	—	1	—	—	1
Lower ,,	1	—	—	—	1
Upper and lower lobes	2	2	1	—	5
Middle and lower lobes	1	—	—	—	1
					25

(b) Without cavitation.

Site.	0–2	2–5	5–10	10–14	Total.
Apex	—	3	4	—	7
Upper lobe	1	—	—	—	1
Upper and lower lobe	—	1	1	2	4
					12

Chronic Tuberculosis together with Acute Pneumonic Condition.

Site.	0–2	2–5	5–10	10–14	Total.
Acute broncho-pneumonia	4	3	2	2	11
Acute miliary	1	3	1	2	7
					18

Acute Pulmonary Tuberculosis without Chronic Lesions.

Site.	0–2	2–5	5–10	10–14	Total.
Broncho-pneumonia	9	7	5	2	23
Miliary	1	2	2	3	8
					31

In five of these cases the broncho-pneumonic consolidation was evidently due to a direct spread from a caseous bronchial the symptoms indicated. Throughout the afebrile period tuberculin Beraneck was administered in small doses, none being above 0·8 c.c. of No. 6 dilution. It never produced a reaction, and certainly, coupled with other attendant factors, gave the impression that it helped to increase the resistance of the patients and enabled them against big odds to fight their way to the satisfactory recovery they have made.

THE TECHNIQUE OF EXCISION OF CERVICAL RIBS.

By A. S. BLUNDELL BANKART, M.C. Cantab.,
F.R.C.S. Eng.,

SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, THE
HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, ETC.

The patient, a female aged 33, was admitted to the Maida Vale Hospital under the care of Dr. Wilfred Harris in January, 1912, with the following history. Her symptoms began more than three years ago with pain in the right shoulder, which she had for two years before she sought medical advice. The pain was worse on exertion. She also had "pins and needles" sensations in the ulnar side of the right forearm and hand, but the distal symptoms were slight compared with the pain in the shoulder. She was first treated by hot-air baths and electricity for "neuritis," and while having this treatment she developed pain in the neck, which was very much worse than the original pain in the shoulder. She was then sent to a hospital, where an operation was performed for cervical rib in June, 1910 (18 months before I saw her). A transverse incision was made very low down on the right side of the neck; the rib was not removed, but "a small spike of bone was chipped off from somewhere"—presumably the tip of the rib. Her symptoms were aggravated by this procedure. On admission to the Maida Vale Hospital 18 months later she had continual pain in the right side of the neck and over the right shoulder. The extremity of the cervical rib was palpable and very tender. There was no wasting of the hand muscles. The skiagram showed a well-marked cervical rib on each side, but there were no symptoms referable to the left. On Jan. 8th, 1912, I removed the right cervical rib through a *posterior* incision.

Operation.—An incision about 4 inches long was made parallel to, and about an inch from, the spinous processes, with its centre opposite the seventh cervical vertebra. The trapezius was divided in the same line and drawn outwards so as to expose the deep muscles at the back of the neck. The outer margin of these deep spinal muscles then led straight to the transverse processes, and so to the cervical rib at its origin from the seventh cervical vertebra. The rib was divided at once close to the vertebra, and, being then *movable*, it was dissected out from the soft parts with the greatest ease. The trapezius was sutured with catgut, and its limited division gave rise to no subsequent weakness or other disability. There was practically no bleeding, and the wound was closed without drainage. The patient was relieved of all her symptoms and has since remained perfectly well.

As regards ease, rapidity, and *safety*, this operation compares very favourably with those that are usually performed for cervical ribs. Two operations are in common use: (1) the traditional operation through an incision on the front of the neck just above the clavicle; and (2) that through an incision at the side of the neck. The first of these was originally an exploratory operation. But nowadays cervical ribs are always diagnosed with certainty, by X rays, before operation. A cervical rib is a process of bone attached to the spine (seventh cervical vertebra), and the aim of the operation is to get at its vertebral attachment to divide it. It seems strange, therefore, that one should elect to approach it through an incision on the front of the neck, about as far away from the spine as possible. In operating from the front, one has to traverse nearly the whole thickness of the neck in order to reach the spine, and the field of operation is surrounded by important structures which cannot be retracted with impunity.

In both the anterior and the lateral operations the rib is immovably fixed, behind, up to the very last stage of the dissection. Consequently, all the soft parts have to be separated and drawn away *from* the rib before it can be resected. This manipulation and retraction of important parts are responsible for nearly all of the unfavourable sequelæ which may follow these operations. The difficulties and dangers, and therefore the accidents and failures, of operations on cervical ribs are due almost entirely to a technique which necessitates manipulation and retraction of the surrounding parts from a rigid *immovable* structure.

The great feature of the posterior operation is the early mobilisation of the rib. In this operation the rib is divided at the very beginning of the deep dissection; all preexisting tension on the soft parts is at once relieved; and, as the rib is now freely movable, it is dissected *from* the soft parts with the greatest ease, and without risk of injury *to any important structure. By displacing* the rib the manipulation of other parts is reduced to the minimum. As the rib is divided close to the vertebra in full view of the operator, there is no fear of its removal being incomplete. The limited division of the trapezius close to its origin from the spinous processes gives rise to no subsequent disability if it is sutured at the end of the operation, and the incision is too far back to interfere with its nerve supply or with that of the rhomboids. In this operation the rib is approached by the shortest possible route, and the dissection is then directed solely to the structure to be removed.

The case was shown at a meeting of the Clinical Section of the Royal Society of Medicine on Feb. 14th, 1913.

Devonshire-street, W.

CASE OF

EPITHELIOMA OF THE AURICLE AND CERVICAL GLANDS; REMOVAL OF AURICLE AND GLANDS.

By NORMAN PATTERSON, M.B. Edin., F.R.C.S. Eng.,

ASSISTANT SURGEON, THROAT HOSPITAL, GOLDEN-SQUARE;
REGISTRAR, THROAT DEPARTMENT, LONDON HOSPITAL;
SURGEON, THROAT AND EAR DEPARTMENT,
CROYDON GENERAL HOSPITAL.

The patient was a man aged 61. He said that his right ear had been injured six months previously by a piece of wood striking it. The outer aspect of the auricle presented an indurated non-ulcerated area, raised above the surface and of about the size of a shilling. It was *situated above* and behind the orifice of the meatus, but did not actually encroach upon it. Under the microscope the growth showed the structure of a typical epithelioma. The glands in the upper part of the right anterior triangle were definitely enlarged, and a very considerable mass lay high up underneath the sterno-mastoid.

An operation was performed in May, 1912. The auricle, together with the skin and soft structures over the mastoid and the membrano-cartilaginous part of the meatus, was removed in one mass. It was thought there might be trouble with the jugular vein where it was overlaid by enlarged glands close up to its exit from the skull, so I determined to expose the lateral sinus and temporarily occlude its lumen. This was done in the usual way by removing a considerable portion of bone with hammer and chisel. Ribbon gauze was then packed between it and the skull wall. In this way the blood flowing into the jugular vein from the cranial cavity was all but cut off. From the lower limit of the wound left by removal of the auricle an incision was made along the whole length of the anterior border of the sterno-mastoid. The internal jugular vein was now exposed low down in the neck and divided between ligatures. A large portion of the sterno-mastoid was removed, and this, together with the glands, fascia, and jugular vein, was dissected from the carotid artery and other structures in an upward and forward *direction. The* common facial vein was early secured. The glands were intimately adherent to the jugular vein almost up to its emergence from the foramen. The vein was ligatured and divided close up to the base of the skull. The spinal accessory nerve ran through the glandular mass and had to be sacrificed. It was also found necessary to remove a portion of the parotid gland, which necessitated cutting some twigs of the facial. Since there were shotty glands low down in the neck in the region of the upper part of the brachial plexus, a dissection of this region was made, and the fascia and glands removed. The wound was drained through a separate posterior opening. The neck healed by first intention. There was a large cavity in the region of the ear which rapidly filled with granulations, and afterwards a skin graft was applied. The patient had facial paralysis for some time, but that has now nearly recovered. The external auditory meatus has been kept as patent as possible by a piece of rubber tubing.

Mr. S. Gilbert Scott, of the London Hospital, has very kindly made numerous applications of X rays as a prophylactic measure. The patient has had two courses of treatment. The dosage and thickness of the aluminium filter have been varied to allow the rays to act both on the deeper and more superficial structures. An interval of a week has elapsed between each administration. So far there is no recurrence. Only 11 months have elapsed since the operation and it is therefore too early to judge as to the ultimate result.

Points of special interest in the case are: 1. Such extensive glandular involvement occurring in association with a comparatively limited growth on the auricle; cancer of the auricle usually shows signs of fairly marked local spread before the glands are much involved. 2. The history of a local injury six months previously is of some interest. 3. I should especially like to lay emphasis on the preliminary occlusion of the lateral sinus practised in this case. This method I have not seen described, and I intend to employ it again in connexion with removal of enlarged glands in cases of malignant disease of the pharynx, tonsil, &c. In these cases it is all important that a thorough clearance of lymphatic structures right up to the base of the skull be carried out, and this is no easy matter if enlarged glands lie along the upper course of the jugular vein. The preliminary exposure of the sinus need not take more than from 5 to 10 minutes.

A skin incision similar to that employed in the mastoid operation, or one with its convexity forward is made over the mastoid process. The periosteum is separated from the upper part of the process and an opening made in the skull three-quarters of an inch behind the centre of the external auditory meatus. This will be effected more easily, I think, with the hammer and chisel than with the trephine. The chisel must be applied obliquely to avoid injury to the wall of the vein. Once the sinus is exposed the opening is enlarged in a backward and upward direction to allow the gauze packing being inserted. In exposing the sinus its varying position must be kept in mind, and also that it may be overlaid by dense or cellular bone. It will, as a rule, be unnecessary to open the mastoid antrum. If the incision over the mastoid be made one with that in the neck the structures in the region of the digastric fossa will be more easy of access. In most cases, after removing the tampon, the soft tissues would be allowed to fall over the cavity and sutured in position. The time spent in this little introductory operation will be amply repaid when one comes to deal with the upper part of the internal jugular, for one can then proceed with confidence, knowing that a nick or tear in the vein will not mean flooding of the wound with venous blood. This is a most disconcerting accident and might easily occur in cases where the vein is adherent to enlarged and indurated glands. Much time may be wasted, and infected tissues unnecessarily cut into, in trying to dissect the glands off the vein. It is better practice to clear away the glands and vein together, and if necessary cut the latter across before applying a ligature. The risk of placing a tampon on the lateral sinus is practically *nil*. I have heard of the jugular vein being torn or injured close up to its exit from the skull. In such a case, after stopping the hæmorrhage temporarily with firm packing, the sinus might be exposed, occluded, and the operation in the neck proceeded with.

If this method were used in combination with a clamp on the carotid, as carried out by Crile, the field of operation could be rendered practically bloodless.

Brook-street, W.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Clinical Cases and Pathological Specimens.

A MEETING of this section was held on March 28th, Dr. J. WALTER CARR, Vice-President, being in the chair.

Dr. FREDERICK LANGMEAD showed: 1. A case of Tremor (? Congenital). The patient, a girl aged 10 years, had definite tremor of both upper limbs, moderate in amplitude. It interfered somewhat with school work, but otherwise caused no discomfort. It had been noticed particularly during the last two to three years, but probably dated from infancy. There were no signs of organic nervous disease. 2. A case of "Nervous Cretinism." The patient was a boy, aged 10 years. He was an undersized and mentally deficient child who first attended the Hospital for Sick Children, Great Ormond-street, when 7½ years old, and then exhibited the usual signs of cretinism to a moderate degree. He could not sit alone, stand, or talk, and was "dirty in his habits." His appearance was characteristic. Under thyroid treatment he had improved considerably in his general condition and could walk, although badly, and became clean in his habits. His vocabulary was still very limited and pronunciation imperfect, only a few simple words being used and these in a monotone. He had lost most of the aspect of cretinism. The feature of special interest was a coexisting cerebral diplegia affecting chiefly the legs. These were stiff, adducted, and their deep reflexes were exaggerated. The plantar response was sometimes definitely extensor. The arms were little, if at all, affected; the triceps jerks were brisk and (?) slight rigidity was present. He stood in the knock-kneed position, with feet abducted, and walked with [illegible] progression. The thyroid [illegible] that he had called the [illegible] jor Robert McCarrison, I.M.S., who had described the association of cretinism with spastic paralysis in his study of endemic cretinism in the valleys of Chitral and Gilgit in India. That writer regarded the paralysis as part of thyroidal inadequacy, and had obtained some success with thyroid therapy in such cases. 3. A case of Defective Ossification of the Skull in a boy. There was marked pulsation over the posterior end of the interparieta [illegible] cerebral in origin and transm [illegible]

Dr. F. G. [illegible] A. BOYD showed a case of Congenital Thoracic Deformity. The patient, a boy aged 6½ years, was the subject of congenital thoracic deformity affecting the right side. There was a large depression in the upper part of the front of the chest, and an oval gap could be made out in the bony parietes, measuring 4 inches in its long diameter (which passed obliquely downwards and forwards from the axilla) and 3 inches transversely. The defect was apparently due to absence of the anterior portions of the second, third, and fourth ribs. The fourth rib appeared to join the fifth. The sternum was asymmetrical, and the right upper costal cartilages, which were attached to the sternum, were bent backwards. There was a marked hernia of the right lung. The clavicle and scapula were smaller on the right side than on the left. There was scoliosis of the dorsal vertebræ, convex to the right. The pectoralis major was fairly well developed, but was not so large as on the left. The pectoralis minor and the upper part of the serratus magnus were apparently absent. There was some depression of the corresponding area of the left side of the chest, but no bony defect. The exhibitors said that the condition appeared to fall within the category described by Dr. J. Thomson in "Teratologia" (January, 1895) as "congenital thoracic deformity." As in Dr. Thomson's cases, if the arm were flexed at the elbow and the hand placed on the front of the opposite shoulder, the deformed area was found to be almost exactly covered by the upper arm. So far, then, Dr. Thomson's suggestion, that this kind of deformity was due to intra-uterine malposition, was supported.

Mr. A. S. **BLUNDELL BANKART** showed a case of Achondroplasia. The patient was a girl aged 7 years. The parents were first cousins. The condition was first noticed in infancy. The child had been treated for rickets when 16 months old, and the treatment had been continued for three years without effect. She was stunted in growth. The head was normal, not rickety. The teeth were good, dentition not being delayed. The chest was narrow, the sternum being prominent (pigeon-breasted) Very slight beading of the ribs was present, and a well-marked horizontal sulcus traversed the lower part of the chest. Lordosis existed. Upper extremities: great enlargement of epiphyses; skiagrams showed marked irregularity and "cupping" of epiphyseal lines; diaphyses stunted. Extreme laxity of wrist-joints was present, yet she had a good grip and could use the hands well. There was looseness of the elbows; the head of the radius on each side could be dislocated and replaced with ease. The lower limbs were very slightly affected, the epiphyses being hardly, if at all, enlarged; the diaphyses were not stunted. There was slight genu valgum which had improved by treatment.

Mr. **LIONEL E. C. NORBURY** showed a case of Circumscribed Serous Meningitis. The patient was a male child, aged 13 months, admitted to the Belgrave Hospital on August 6th, 1912. There was a history of convulsions 15 days previously, followed by right facial paresis and tremor of the right hand. No history of trauma was obtained. An abscess on the left side of the neck had been incised two months before admission, and discharge from the right ear occurred at the same time. On admission he was seen to be a well-nourished but very pale child. There was a fine, regular tremor affecting the right arm and hand, right leg, right side of mouth, and also the tongue and lower jaw. Right facial paresis and slight convergent strabismus were present. The knee-jerks were present and equal, not exaggerated. The abdominal reflexes were present. Lumbar puncture failed to withdraw fluid. No changes were seen in either fundus oculi. At an operation the left parietal bone was trephined over the centre of the Rolandic area, and the opening in the bone enlarged so as to freely expose this area. The dura was incised crucially and the pia-arachnoid found to be very swollen and œdematous. The pulsation was feeble. The tremor gradually disappeared, first from the leg and then from the arm and face. The wound healed by first intention. Cerebrospinal fluid collected under the scalp-flap and was evacuated every few days (five times in all) until it ceased. Nine days after the operation there was no sign of tremor. The patient was seen on March 20th, 1913, when the general condition was found to be very good. A very slight facial weakness remained. In the region of the craniotomy wound there was a moderate degree of bulging.

Dr. **R. C. JEWESBURY** showed a case of Acute Poliomyelitis affecting the Muscles of both Hands. The patient, aged 12 years, had an attack of "influenza" six months ago, being very feverish for two days; she then became very weak in the right arm, and to a less extent in her back and right leg. She showed marked wasting of the muscles of both hands and also wasting of the muscles of the right arm and shoulder. The triceps was the muscle most affected in the arm.

Dr. **F. PARKES WEBER** showed a case of Congenital Eversion of the Great Toes and other Abnormalities. The patient was a healthy-looking female baby aged 7½ months Both great toes were everted and overlapped by the other toes, and the deformity thus produced suggested at first sight the eversion of the great toes not rarely met with in elderly persons, often associated with ulnar deflexion of the fingers and often wrongly ascribed to the wearing of badly shaped boots or shoes. Both the child's thumbs were turned inwards across the palms, and there was also an abnormal projection on the left side of the neck. The patient, who seemed otherwise quite normal, was the only child of healthy parents both young. There was no history of any similar malformation in any other members of either the mother's or the father's family, nor was there any definite history of "maternal impression."

Dr. **LEONARD G. PARSONS** showed Sections from a Case of Progressive Muscular Atrophy (Werdnig-Hoffmann Type) in a male child aged 3 years. He had been normal until aged 10 months, when progressive wasting began. This was first observed in the shoulder muscles and the upper part of the thigh. Ability to hold the head erect was lost in the third year. On admission to hospital the cranial nerves were normal. There was almost complete flaccid paralysis of the shoulder-girdle muscles, double wrist-drop, and supination was impossible. Movements of the fingers was possible but feeble. The lower limbs showed wasting, chiefly above the knees, and contractures, the only movements possible being flexion and extension of the ankles and toes. The abdominal and intercostal muscles were paralysed. He was unable to sit up alone or hold the head erect. Scoliosis was present in the lower dorsal and lumbar regions. Knee-, ankle-, and arm-jerks, and abdominal reflexes were absent. There was no sensory change. The cerebro-spinal fluid was normal. There were marked diminution of electrical excitability and slight reactions of degeneration. Death was due to broncho-pneumonia. *Post mortem.*—Subcutaneous fat was present in fair amount and masked some of the muscular atrophy. The affected muscles were very pale and atrophic, the diaphragm by contrast being a good colour. The muscles showed fibrosis. Some of the muscle fibres were larger than normal and had a rounded contour; the majority of the altered fibres were smaller than normal (0·01 mm. and less), and some were on the point of complete atrophy. The small fibres showed an enormous increase in the number of nuclei. Striation was well preserved and muscle spindles were normal. Many fibres showed fatty degeneration. The anterior nerve roots were smaller than normal and showed overgrowth of fibrous tissue. Nissl sections of the cord showed a striking diminution in the number of cells in the anterior horn, about one-third the normal number being present. The cells were also smaller than normal and their processes less marked. Some showed a degree of chromatolysis. Marchi sections showed no change.

Dr. **PARSONS** also showed specimens of Diffuse Sarcomatosis of the Brain and Spinal Cord. They were from a child aged 2 years. Symptoms started four months before death. The initial symptoms were headache and violent screaming attacks with gradually failing vision, and at the end of three months the child was blind. Walking was normal until 14 days before death. Hearing, speech, and intelligence were normal until the onset of the final pressure signs, which commenced 10 days before death. At the post-mortem examination the cord was found to be ensheathed throughout its length by growth, which also invaded its posterior aspect. The growth extended on to the nerve-roots and there were many growths on the cauda equina. It extended outside the spinal canal along the root of the lumbar plexus The Gasserian ganglion and the ganglia of the ninth and tenth cranial nerves were much enlarged, and the seventh and eighth nerves were thickened by an extension of the growth. Multiple small growths were present over the base of the brain arising from the pia-arachnoid. Hydrocephalus was marked. The primary growth was in the cerebellum, and had invaded, distended, and completely filled the fourth ventricle; it had also blocked the iter, and then was continued as a filmy gelatinous covering over the ependyma of the third ventricle. Microscopically, the growth was a mixed-celled (chiefly small-celled) sarcoma, and its method of spread was due to "infection" of the cerebro-spinal fluid.

Mr **SEYMOUR G. BARLING** showed a Hair-ball removed from the Stomach of a child. The specimen consisted of a felted mass of hair and string, and presented an exact cast of the stomach, showing the pyloric canal, pyloric antrum, and fundus. It was removed from a female child aged 7, of normal intelligence, who for some days before operation had suffered from pain in the upper abdomen and vomiting. On examination a tumour exactly resembling the shape of the stomach presented itself in the epigastrium and moved up and down on respiration. The shape of the tumour, together with a history of hair biting, extending over several years, and the occasional passage of string, tape, &c., in the motions, led to a direct diagnosis by Lieutenant J. L. Ritchie, R.A.M.C., by whom the case was first seen. On gastrotomy being performed, the specimen was easily removed and the patient made a satisfactory recovery.

HUNTERIAN SOCIETY.

The Uses of Tuberculin.

A MEETING of this society was held on March 26th at St. Bartholomew's Hospital (Library).

Dr. ARTHUR LATHAM opened a discussion on the Uses of Tuberculin with an interesting general survey of the subject. He gave reasons why tuberculin could not be relied on without corroborative evidence in the diagnosis of tuberculosis. The von Pirquet reaction was seldom of service in this direction after the age of 7, but the intensity of the reaction was of service in estimating the dosage and spacing of doses in a course of tuberculin, and the absence of reaction was of some value in excluding tuberculosis. The value of a reaction after hypodermic injection of old tuberculin was also subject to limitations. The important thing was a focal reaction, provided that this was supported by other evidence. Dr. Latham described the class of case in which it was inadvisable to use tuberculin as a diagnostic, and gave his reasons. As to the value of treatment by tuberculin in pulmonary tuberculosis Dr. Latham gave his own impressions, together with the evidence of German and American observers, and especially called attention to the fact that with the use of tuberculin at the King Edward VII. Sanatorium the number of patients who lost their tubercle bacilli had been increased by 17 per cent over what was obtained merely by sanatorium treatment. The value of tuberculin and the methods of administering it in the various manifestations of tuberculosis, such as pleurisy, peritonitis, lupus, and disease of the glands, joints, and bones, were discussed. It was pointed out that if the real nature of pleurisy in early adolescence was recognised and the case properly treated by sanatorium methods and tuberculin therapy probably a considerable number of cases of pulmonary tuberculosis could be avoided. As to the particular form of tuberculin to use, results showed that this was of no great importance; the chief thing was for the observer to know the value and the limitations of the particular brands he used. Dr. Latham drew attention to the value of the new tuberculin in febrile conditions or cases in which autoinoculation readily occurred, and said that in many chronic cases sensitised B.E. was preferable to the ordinary bacillary emulsion. He had never been convinced of the truth of the statement that bovine prepara-
tion and human in examples
result of scientific examina-
roportion of surgical tuberculosis was due to infection from human sources, yet the upholders of cross vaccination treated all cases of this form of the disease with human preparations. The fact that great improvement followed in many of these cases showed that cross vaccination was not essential.

Dr. G. A. CRACE-CALVERT first wished to emphasise what Dr. Latham had said about pleurisy. It should never be treated as of no importance, as more often than not it was followed sooner or later by definite disease. Sanatorium and tuberculin treatment were complementary, the latter providing stimuli to the production of antibodies, and the former the necessary powers of response. The majority of patients proved suitable for the administration of tuberculin if they were carefully watched first and then given very small doses to begin with. He always used the bacillary emulsion, as it nearly corresponded to an ordinary vaccine, was more slowly absorbed, and therefore made a greater and more lasting production of antibodies. He used the intensive system, as he thought that it increased the tolerance and abolished the sensitiveness. When one always used the same site for the injections it sometimes became difficult to inject the dose—apparently owing to the inflammatory condition produced, and when this was the case a general reaction was particularly liable to occur. Even if tuberculin did aid in the production of cavities it was often a good thing, as he considered it preferable to have simply a ring of scar tissue round an empty cavity than a mass of dead tissue containing virulent or living bacilli, and he did not think that this cavity formation made more liability to hæmorrhage, as the focal reaction tended rather to the obliteration of the blood-vessels. Patients treated with tuberculin certainly lost the bacilli from their sputum more readily than those not treated, and so the tendency to relapse was greatly reduced.

Dr. J. W. LINNELL found himself opposed to a careless and indiscriminate use of the subcutaneous test for the following reasons: (*a*) The danger of lighting up quiescent disease; (*b*) the increase of sensitiveness to tuberculin often caused, leading to difficulties in treatment later; (*c*) the fact that even should a focal reaction result there was often nothing to show whether the focus was active or quiescent. In cases of suspected pulmonary tuberculosis the same evidence could be obtained without danger by using tuberculin in therapeutic doses. All the tuberculins were, he thought, broadly speaking, the same tuberculin and the important factor might well be the amount of autogenous tuberculin washed out into the circulation by the focal reaction. He objected to the wilful causation of reactions and wa
of the gentle, gradual method
e type of case suitable for tubercul
was the resistance of the individual. In the treatment of early cases, especially where there was any suspicion of activity, recourse should not be had to tuberculin till after a course of absolute rest and other sanatorium methods. If the symptoms subsided, tuberculin should then be started cautiously. The maximum dose differed with the individual, and there was no point in striving to attain to any particular dose of any particular brand of tuberculin. The following points should be noted as the results of treatment: (*a*) The fact that nothing dramatic occurred, tuberculin merely imitating the natural processes of self-healing; and (*b*) the fact that nothing like complete immunity was conferred by tuberculin. Tuberculin, he added, was of great use in suitable cases, if sanely administered, but should never be looked upon as a substitute for other forms of treatment, while sanatoriums were indispensable adjuncts in any efficient dispensary system.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Nephrectomy.—Location of Pus in the Hand.

A MEETING of this section was held on Feb. 21st, Mr. R. D. PUREFOY, the President, being in the chair.

Mr. C. ARTHUR BALL read a paper on Nephrectomy. He pointed out that the improved methods of diagnosis had greatly reduced the mortality, but there still remained a risk attached to nephrectomy which was probably greater than that of any other major operation—the danger of hæmorrhage. He stated that enough attention was not attached to this danger in the teaching of the subject, and expressed the opinion that the kidney could be more readily reached from the front by an iliac extraperitoneal incision, like that recommended for exposing the lower part of the ureter. This incision could then be extended upwards and backwards in the direction of the external oblique fibres if more room was needed. He stated that this was the incision he always employed, and pointed out that by it the vessels of the pedicle could be readily exposed, and any abnormal vessels could be easily seen and dealt with more safely and easily than by the lumbar incision. In his opinion lumbar nephrectomy should be classed with lumbar colotomy and given up.—Mr. R. C. B. MAUNSELL said that when a student he had seen cases of death from hæmorrhage, but he never had a case himself, and this he attributed to the fact that where he found a kidney very adherent and matted from chronic disease he adopted subcapsular nephrectomy. When the kidney was very adherent he thought it was useless to try and get it out by any other method.—Sir JOHN LENTAIGNE considered that the efficiency of the other kidney was the most important point to look into, and it was always the one that he weighed before operating on a kidney. The fear that the

urine tell. At one time it was thought that by diverting the urine from each ureter into separate channels one could tell whether the other kidney was functioning or not. Ureter catheterisation was the only reliable test, but unfortunately this was a procedure which could not always be easily carried out. Even the most expert men had found it impossible to use a ureter catheter in every case. A procedure which he found efficient was a double incision. By cutting down on both kidneys and palpating one was able to tell whether the kidney and ureter on the opposite side were all right, and the patient appeared to be nothing the worse.—Mr. KENNEDY considered it a very sweeping thing to condemn the lumbar operation, as by combining the incision at right angles with lumbar incision the largest kidney could be taken out. He referred to the use of a clamp for preventing hæmorrhage. If the pedicle of the kidney was taken up and clamped before the vessels were isolated the latter could afterwards be taken up and tied individually. It was, he said, astonishing the amount of room provided by the freeing of the last rib.—Mr. PEARSON said he had seen two or three nephrectomies by the incision described, and to his mind it was the ideal procedure. The ease with which the operator could see what he was doing was very remarkable. —Mr. H. STOKES said that the practice of a surgeon who had performed 40 nephrectomies without a single death was not to tie himself to any particular incision.—Mr. BALL, in reply, said he generally started by laying the patient on the back, inclining the body a little to one side. He usually started with a small incision of about four or five inches, and if there was not room enough he extended it higher up. His object was not so much to try and convert those who had performed lumbar nephrectomy satisfactorily as to show that if students were taught that this anterior incision was a much safer method it would be an advantage.

Mr. A. A. MCCONNELL read a paper on the Location of Pus in the Hand. He pointed out that there were definite spaces in the hand independent of the tendon sheaths in which pus might collect, that the diagnosis of pus in these situations could be made, and that special incisions were required for adequate treatment. He adopted the nomenclature introduced by Kanavel, of Chicago, and in the main advocated the treatment employed by him. Clinical cases were cited, however, which went to prove that adequate drainage of the middle palmar space could be carried out by placing an incision behind the web of one or more of the fingers and introducing a drainage tube. This incision avoided the digital vessels and nerves, and proved as effective as Kanavel's palmar incision.—The PRESIDENT said that the fact that these injuries to the hand were so frequent, and might have such disastrous results if not well treated, invested the subject with the greatest importance.—Mr. L. GUNN said he had felt for a long time that in hospital practice septic fingers and hands were left very much to the residents and house surgeons, and that very disastrous results were often experienced where incisions were possibly made in wrong positions.—Mr. CRAWFORD said that a point of importance was that this method of making an incision of the web of the finger was a new one, and had only been performed by Mr. McConnell himself. He had only one case of the kind since he had learned the method, and in that case, although the whole hand was œdematous, he determined to try drainage through incision of the web of the little finger, and the result was very good, all the symptoms subsiding in three or four days.

SECTION OF OBSTETRICS.

Instrument for Minimising Risk of Septic Infection during Operations.—Exhibition of Specimens.—Uterine Rupture.—Gonorrhœal Vaginitis Treated by Vaccine.

A MEETING of this section was held on March 7th, Dr. HENRY JELLETT being in the chair.

Mr. J. SPENCER SHEILL exhibited an Instrument designed to Minimise the Risks of Septic Infection during certain Gynæcological Operations, and explained its working. In reply to Dr. Jellett he suggested that it would be found useful for the introduction of drainage after subtotal hysterectomy in cases where there was a suspicion of sepsis. —Dr. JELLETT said that personally he would be more inclined to drain through an opening in Douglas's pouch than through the cervix. He thought that the apparatus would be very suitable for this purpose.—Mr. SHEILL said that the object he had in designing the instrument was to avoid the necessity for pulling the probe back after the gauze drain had been introduced. In some cases posterior fornix drainage was not indicated; for instance, in uterine rupture cervical drainage would be indicated, and his instrument would, he considered, be the safest way to drain.

Dr. JELLETT exhibited specimens taken from two cases of Genital Tuberculosis. The first involved the tubes, uterus, and rectum. The patient was an 8-para, aged 58. She complained of hæmorrhage for five months, with pains in the lower abdomen, as a rule, before the hæmorrhage started. She was passing fæcal matter through the vagina. The disease was first thought to be malignant, but an examination of uterine scrapings showed it to be tubercular. On opening the abdomen the uterus was found to be studded with tubercle, and was adherent to the posterior pelvic wall. There was a tumour of the size of a hen's egg in relation to the rectal wall, and adjacent to the uterus. The rectum was resected without separating it from the uterus, which was removed at the same time. The reason for resecting the rectum was that it appeared to be involved in the tumour. On examination of the latter, however, it proved to be a mass of fat and of tubercular growth in the mesentery of the rectum. The lumen of the rectum was considerably reduced. The cavity inside the uterus contained some breaking-down tubercular material. An end-to-end anastomosis of the rectum was done, and held for 11 days, and then began to leak. In the second specimen there was tubercular disease of the tubes associated with carcinoma of the ovaries in a patient aged 32. Dr. Jellett invited opinion as to whether tubercular disease of the tubes was commonly accompanied by tubercular disease of the uterus, and got well after removal of the tubes. Some authors stated that this was usual, but he had previously never found tubercular disease of the uterus that did not eventually lead to serious complications.—Dr. E. HASTINGS TWEEDY said that he could only say that whether the uterus was or was not involved, he had known patients to get well after resection of tubes. While tubercular disease of the tubes was frequently seen, disease of the uterus was rarely met with.—Mr. SHEILL said that he had seen a good number of cases of disease of the tubes of tubercular origin, but only one case of definite tubercular disease of the uterus.—Dr. JELLETT, in reply, suggested, with a view to throwing further light on this important subject, that all operators should examine scrapings from the uterus in all cases of tubercular salpinx.

Mr. SHEILL then read clinical notes of Two Instructive Cases of Uterine Rupture, and these were discussed by Dr. TWEEDY, Dr. D. G. MADILL, and Dr. JELLETT.

Dr. GIBBON FITZGIBBON read a paper on Gonorrhœal Vaginitis treated by Vaccine. He recorded six cases treated by vaccine, five with good results; the sixth had appeared cured, but relapsed or else had been reinfected. He considered that vaccines to be effective should be made from cultures grown fresh from the human host, but that they need not be autogenous. Local treatment, in combination with vaccine, was advisable, and probably necessary—certainly in the chronic cases with mixed infection.—Mr. SHEILL said he considered the paper of extreme importance from the point of view of treatment of gonorrhœal infection in young children, as in such cases there were many difficulties in local treatment, and, therefore, if there was another means of treatment, it should be pushed. He did not think local treatment should be done away with, but he considered vaccines a very useful adjunct.—Dr. MADILL said he had tried many varieties of local treatment, and he thought the best results were produced by protargol. He was struck with the chronicity and difficulty of diagnosis in these cases. He pointed out that Bumm had described five kidney-shaped intracellular diplococci, one of which was Gram-positive, and the other four negative to this stain, and the only difference he knew between these was by culture. He thought gonococcus was very difficult to grow. He went on to describe the methods adopted at Wertheim's clinic for making this vaccine. No case was considered cured until the microscope failed to find anything of the nature of gonococcus in the secretions.—Dr. R. J. ROWLETTE pointed out the great difficulty in treating cases of gonorrhœa in the female owing to the ease with which the infection became mixed. He did not think that the gonococcus disappeared for a considerable time, but it became crowded out by other organisms, and was not easily found. In some cases of gonorrhœa in the male that came under his notice it was found necessary to treat with staphylococcus after treating with gonococcus vaccine. A point of importance was that the vaccine should be made from a fresh culture. This he considered of more importance than that the vaccine itself should be fresh, although vaccine kept for a long time did lose in efficacy.—Dr. W. D. O'KELLY said that in some cases it was very questionable whether the infection was really gonococcal. He never succeeded in getting gonococcus to grow.—Mr. HENRY MOORE said that in the cases in which vaccine was most useful—namely, at the very beginning of an attack, or in old-standing cases of gleet—an autogenous vaccine was impossible. His method of obtaining a vaccine was to get Dr. Stokes to make one once a month from a male case on the second day of the urethritis. If in doubt as to the cause of an old-standing discharge or the cure of a patient who had suffered from gonorrhœa he gave from 15,000,000 to 30,000,000, and examined the resulting discharge, if any, 24 hours after. In old-standing cases of posterior urethritis no local treatment was effective without vaccine, and the serum should not be more than four weeks old.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 26th, Dr. John Lindsay, the President, being in the chair.—Professor J. H. Teacher gave a demonstration of gynæcological specimens illustrating various conditions, the most noteworthy being sections of the genital gland of a case of hermaphroditism showing both ovarian and testicular tissue elements, specimens of ovarian pregnancy, and a specimen of a uterus showing ectopic pregnancy in a rudimentary Fallopian tube. A lantern demonstration was also given on the embedding and development of the early human ovum. Professor Teacher reviewed the present state of our knowledge of the subject, more particularly in relation to the work of Professor J. H. Bryce and himself. The lecture was illustrated by numerous lantern slides and by microprojection of sections of the Teacher-Bryce ovum. Professor Teacher stated that the preparation still represented the earliest known stage of the human ovum, the only more recent specimen at all comparable in age being that of Young, of Edinburgh, which is apparently intermediate in development between it and the ovum of Peters, but probably abnormal. Several very valuable ova of about the age of the last have been found within the last five years, and the examination of these has confirmed and extended the discoveries due to that famous preparation. Professor Teacher also reviewed the position of the theories of the nature of menstruation and its relation to ovulation and fertilisation.—The discussion which followed was taken part in by Dr S. Sloan, Dr. E. H. L. Oliphant, Professor J. M. Munro Kerr, Dr. G. Balfour Marshall, and the President.

Reviews and Notices of Books.

Instinct and Experience. By C. LLOYD MORGAN, D.Sc., LL.D., F.R.S., Professor in the University of Bristol. London: Methuen and Co., Limited. 1912. Pp. 299. Price 5*s.* net.

Professor Lloyd Morgan, as readers of his earlier writings are aware, possesses in a remarkable degree the capacity for devising apt and clear definitions, and this capacity finds ample scope in the discussion of the questions with which he deals in his latest volume—questions which owe their difficulty in no small degree to the divergence of meaning attached by different writers to the terms used in the debate. It is the more necessary to remove this source of confusion because, as the author very justly points out, our views with regard to the nature of instinct—and these views are necessarily expressed in the definition of instinct which we adopt—imply to a large extent the whole character of our philosophical outlook. Professor Morgan, approaching the question as a biologist, would define instinctive behaviour as "that which is, on its first occurrence, independent of prior experience; which tends to the well-being of the individual and the preservation of the race; which is similarly performed by all the members of the same more or less restricted group of animals; and which may be subject to subsequent modification under the guidance of experience." On the ground of physiological experiment he would conclude that such behaviour is the outcome of inherited subcortical dispositions, being, in fact, of the nature of more highly complex reflex action, and as such within the capacity of the decerebrate animal. But in the normal animal with intact brain this behaviour, though in itself automatic, is accompanied by conscious experience, and the experience so begotten reacts on subsequent behaviour, which then, in so far as it is modified or in part conditioned by such reaction, becomes intelligent. The conscious guidance implied in intelligent behaviour is in the higher vertebrates correlated with functional activity in the cortex. It may be noted in passing that this restriction of the term instinctive to the expression of subcortical dispositions would exclude from the category of instincts those hereditary mental tendencies, shown, for instance, by men of genius, which are very commonly spoken of as instinctive. Professor Morgan would explain such tendencies as due also to congenital dispositions—to dispositions, however, not of the subcortex, but of the cortex—and he would qualify them as innate. This sharp distinction drawn between innate tendency and instinct appears to be warranted by physiological experiment, and the use of distinctive terms to describe the two classes of facts is practically very convenient.

Professor Morgan's doctrine of experience, which it is the special aim of this work to expound, is the development of his view of the relation of instinct to intelligence. The first experience given to the higher vertebrate is that which accompanies instinctive behaviour; we have at that stage the beginning of the synthetic process of experiencing, correlated with the synthetic process of living, which is its natural precursor. The essential characteristic of this higher level of living is that new relationships supervene, which we describe as conscious. Is there any sufficient reason for separating these relationships, as subjects of scientific inquiry, from the rest of the world-process? To this question Professor Morgan's reply is an emphatic negative. In his view the province of science is to deal with process and its products as somehow existent; it is not concerned with their *source*, which is a question for metaphysics. And if science has simply to accept chemical and physical processes, gravitative or crystalline processes, without attempting to explain their source, so also has it to accept conscious processes as within the constitution of nature. In holding this monistic doctrine Professor Morgan is, of course, at issue with the supporters of vitalism and animism, but he appears to be even more removed from sympathy with the advocates of what are commonly regarded as mechanistic theories. This is clearly evident, for instance, in his dismissal of the epiphenomenalist view of consciousness, and in his insistence on the innovating and incalculable trend of evolution. In his treatment of this latter point his attitude, indeed, despite the fundamental differences in their doctrines, approximates very much to that of M. Henri Bergson; and we may add that Professor Morgan is ungrudging in his recognition of the services which he considers that the French philosopher has rendered to science by his destructive criticism of the intellectualist position. This capacity to sympathise with and to understand the views of opponents is no small element in the effectiveness of Professor Morgan's argument, and it is shown in the examination of doctrines the most alien to his own tendencies.

The book is altogether a remarkable contribution to psychological literature, and even those who cannot accept all the author's conclusions may feel grateful to him for the clarifying influence which his work must exercise on the discussion of the difficult and complex questions that it deals with. The book, as we learn from the preface, was in some measure suggested by a discussion on the subject of Instinct and Intelligence which took place two years ago in London at a joint meeting of the Aristotelian and British Psychological Societies and of the *Mind* Association. The fact is worth noting for the encouragement of the organisers of such intellectual tournaments, which can certainly not be held fruitless if they help in any way to stimulate the production of works of the value of this singularly acute and penetrating study.

Researches in Colour Vision and the Trichromatic Theory. By Sir WILLIAM DE W. ABNEY, K.C.B., D.Sc., D.C.L., F.R.S. With four coloured plates and other illustrations. London: Longmans, Green, and Co. 1913. Pp. 418. Price 21*s.* net.

WE have no hesitation in saying that this book is the most important contribution to the study of colour vision, normal and diseased, that has appeared for a long time. Those interested in the subject know that Sir William Abney has for many years been publishing researches on it in the Proceedings of the Royal Society and elsewhere. It is not easy to keep closely in touch with periodical publications of this kind, and we cordially welcome this authoritative exposition of his work, which gathers together the scattered threads and gives a connected account of the distinguished author's views. These views are strongly opposed in certain quarters, and this is an exposition of the work, and the deductions from that work, of one man.

The originality of the methods of attacking the problems, both in their conception and in their practical working out, will appeal to every scientist. They are scarcely open to criticism, though criticism is not only justified but would certainly be welcomed by the author in the interpretation of the results. Sir William Abney is scientifically the lineal descendant of Thomas Young, Helmholtz, and Clerk Maxwell. All were physicists, and all, great men as they were, were most vulnerable on the physiological side. The Young-Helmholtz theory of colour vision is, *par excellence*, the physicist's theory. Let us admit at once, with Sir William Abney, that it does not satisfactorily explain all the problems. At least it explains many, perhaps most, and in any case we sympathise with the author's wish "to show that the trichromatic theory of colour vision does not yet require a funeral oration over its remains." As he says again, "A theory, to be one of perfection, must offer the truth, the whole truth, and nothing but the truth. The trichromatic theory offers the truth: but the physiologists must add their quota to it to make it the whole truth." This is a safe and reasonable standpoint.

Colour vision and its defects have an important practical bearing on everyday life, but they appeal to a relatively small number of medical men. Those interested in the subject are bound to read this book, and it will be found that it is not all easy reading. Sir William Abney's writings are not always as lucid as they might be, though this book is much less obscure than some of the original papers upon which it is largely based. There is one irritating feature which we should like to see altered. All the statistics and diagrams are referred to an arbitrary scale, which necessitates reduction to wave lengths by the reader. They might equally well have been recorded in wave lengths and thus made universally available. The specialist will find most to interest him in Sir William Abney's new method of numerically estimating colour deficiency in the colour blind, but the facts upon which it is based are by no means accepted by all.

Studies in Clinical Medicine. By C. O. HAWTHORNE, M.D. Glasg., Physician to the North-West London and Royal Waterloo Hospitals. London: John Bale, Sons, and Danielsson. 1912. Pp. 441. Price 6*s.*

THIS is a volume of essays and lectures of varying interest, many of which have already appeared in the current medical journals, but all have been revised and some of them have been partly rewritten.

The first five essays deal with different aspects of rheumatoid arthritis and contain some interesting observations on various aspects of this disease, including the occurrence of heart disease in connexion with "rheumatoid" joint disease. Reproductions of excellent photographs are given, showing the deformities that may ensue. One of the articles bears the title, "On the Occurrence of Pyrexia in Cancer and Other Diseases of the Liver and in Cases of Gall-stone." The fact that pyrexia may accompany malignant disease not only of the liver but of other organs (e.g., the lungs) is important, and unless it is fully recognised errors in diagnosis are likely to arise. Dr. Hawthorne records some cases in which the temperature was a confusing element in diagnosis. In one case it was not only the mere occurrence of pyrexia which was of interest, but also the course and character of the fever, and the fact that on many occasions each of the sharp, short-lived outbreaks of fever was preceded by a severe rigor. It has been suggested that "the absence of ague-like attacks" favours a diagnosis of malignant disease, but the cases quoted show that such a proposition does not always hold. Reports are given of several clinical lectures and demonstrations. One which is well worthy of attention is on "Two Cases of Chronic Renal Disease associated with Secondary Inflammation of the Serous Membranes." Dr. Hawthorne draws attention to the well-known fact that a patient with chronic interstitial nephritis may reach an advanced stage of the disease without any symptoms causing him anxiety or even annoyance. The first active manifestation of this disease may be an acute pleurisy. We agree with Dr. Hawthorne that it is not too much to say that an acute pleurisy occurring in a patient who has reached middle life is an event which ought in itself to excite a suspicion of kidney disease. Exactly the same remark may be made of pericarditis, and in this instance there may not only be an absence of fever, but also absence of pain.

We have found much of interest in this volume. There is evidence of careful observation and also of the power to describe and record clinical conditions. Much instructive material is gained by records of bed-side teaching; the observations at the bed-side form the most valuable information a student can obtain, both for examination purposes and subsequently to aid him in the actual practice of his profession.

Trommelfellbilder. Ein Atlas für den Praktischen Gebrauch. Herausgegeben von DR. A. PASSOW, o.ö Professor an der Friedrich Wilhelms-Universität und der Kaiser Wilhelms-Akademie fur das Militärärztliche Bildungswesen zu Berlin. Mit 26 farbigen lithographischen Tafeln. Jena: Gustav Fischer. 1912.

FOR beauty and truth of tint and accuracy of drawing it is probable that most of these coloured lithographs have never been equalled. We endorse Dr. Passow's approval of the drawings, which are from the pencil of Herr Helbig. As an aid to instruction, but to individual instruction alone, they would be invaluable, but for the assistance of the practitioner who wishes information the same scarcely applies. For the latter either does not know enough to enable him to find the counter part of the case he desires, or he knows enough not to require such an illustration. The potential value, therefore, of this artistic production is low ; its artistic merit high As the science and art of aural surgery and therapeutics advance, so is the need for works of such a description as Dr Passow's diminished Less importance is attached to trifling variations of the size, shape, and position of the cone of light, the colour of the tympanic membrane, and such like minutiæ, which form the bulk of the limner's stock in trade

This is quite the finest atlas of drawings of the tympanic membranes published of recent years.

Lehrbuch der Chirurgischen Operationen an der Hand klinischer Beobachtungen fur Aerzte und Studierende Von Professor Dr FEDOR KRAUSE, Geh Medizinalrat, dirigierendem Arzt am Augusta Hospital in Berlin, in Gemeinschaft mit Dr EMIL HEYMANN, Oberarzt am Augusta-Hospital 1 Abteilung, mit 233 zwei- und mehrfarbigen Abbildungen auf 65 Tafeln, sowie 57 Figuren im Text Berlin und Wien Urban und Schwarzenberg 1912 Pp 252 Price, paper, 12 50 marks, bound, 14 marks

THIS is the first instalment of an elaborate and valuable treatise on operative surgery, and this section deals with the general preparations for an operation, the methods of obtaining anæsthesia, both local and general, the principles of asepsis, the sterilisation of the hands of the surgeon and his assistants, of the skin at the site of the operation, the dressings, and the suture material The treatment of complications, such as heart failure, and pain after the operation is also considered After these preliminary matters have been dealt with the surgery of the head is treated, and that is the only section of operative surgery contained in this part It begins with an account of wounds of the head, including fractures, then follow the removal of tumours of the face, the plastic operations on the face, the surgery of cleft palate, and rhinoplasty The section on the surgery of the eye includes only enucleation of the bulb, operations on the lids, and osteoplastic resection of the outer wall of the orbit Descriptions of the operations of the ear and nose are given, and are followed by a very full account of the surgery of the fifth nerve, including resection of the Gasserian ganglion The majority of the operations described are illustrated with black and white or coloured plates, and these have been executed in a very satisfactory manner

This work has been designed and carried out admirably We await with interest the succeeding parts, for it should prove to be a most complete treatise on operative surgery

---

Hygiene for Health Visitors, School Nurses, and Social Workers By C W HUTT, M A., B C Cantab, D P H Oxon London P S King and Son 1912 Pp 415 Price 7*s* 6*d* net

THE health visitor now takes a recognised and important position among sanitary officials In many of our larger towns health visiting alone occupies the time of several women on the establishment of the medical officer of health's department, in other places health visiting and school nursing are combined, while in rural areas the county district nurses are sometimes very usefully employed by local authorities to give assistance in these branches of sanitary work

It is, however, by no means easy to answer the question, What should a health visitor know? Every medical officer of health, and, indeed, every medical practitioner, can at once name dozens of things which she can do, to the great advantage of the working class households which she visits, and perhaps almost as many things which she should not do Usually a nebulous compromise is effected by saying that it all depends upon the woman herself, and that the most essential qualification is "tact" But if tact is to be truly exercised it must be based on knowledge, not only of the particular details and rules which the visitor is to attend to as part of her instructions, but of the essential principles which underlie them Here, however, we enter upon the chief difficulty which confronts those who undertake to examine and give certificates to health visitors How far can the examiner reasonably go in insisting on genuine knowledge and rejecting the spurious substitute afforded by the more or less accurate recital of semi-scientific tags which are only imperfectly understood? At present the examination standard is necessarily dependent partly on the kind of knowledge which candidates as a whole are found to possess and partly on the teaching available

It is from the latter point of view that we must give a very cordial commendation of Dr Hutt's work While in its subjects it follows the articles of the syllabus of the examinations for health visitors held by the Royal Sanitary Institute it is in no sense a cram book A study of any one of its chapters shows that Dr Hutt has given great pains to the selection of the subjects with which he deals, and to the accuracy of the instruction which he gives, and that he has nowhere lost sight of the purpose for which his book is intended Women of good general education, especially if it includes some knowledge of elementary science, who are intending to follow this line of municipal work, could not do better than master the contents of this volume It should not only give them all the information requisite for examinations such as those of the Royal Sanitary Institute or National Health Society, but also should ground them, when they come to undertake practical work, in the principles which they have to apply, so that they will carry it out with a proper sense of proportion We may add that there is much information in this volume which will be found of great value to those engaged in private nursing

---

Cerebellar Functions By Dr ANDRÉ THOMAS, Ancien Interne des Hôpitaux de Paris Translated by W CONYERS HERRING M D New York With 89 figures in the text Nervous and Mental Disease Monograph Series, No 12 New York Journal of Nervous and Mental Diseases Publishing Company 1912 Pp 223 Price $ 3 00

SINCE the appearance of his well known Thèse in 1897 Dr André Thomas, of Paris, has been regarded as one of the authorities on the physiology and pathology of the cerebellum and he has justified this opinion by many other valuable communications on this difficult subject In a recent monograph he has given a very complete *résumé* of the state of present knowledge on the anatomy and physiology of the cerebellum, and on the symptomatology of cerebellar disease, and it is this monograph which now appears in an English translation, and will, we feel sure, be welcomed by a large circle of readers The first section of the book is taken up with an exposition of the clinical facts and experimental phenomena that are found to result from interference with the functions of the cerebellum The second part is concerned with their interpretation While it is evident throughout that the material is being handled by one who is a master of his subject, we wish especially to commend the second division of the book, and in particular the chapter on the cerebellum and motility, which contains a judicial investigation of the claims of rival hypotheses to consideration

The physician in search of knowledge in this department of medicine will find this monograph to contain a complete and up to date presentation of the subject, lucidly set forth and unencumbered by non essentials The translation is on the whole well done, but it bears evidence of a certain amount of haste, for several slips have crept in, and the rendering of the original is not always satisfactory.

Cancer of the Breast Clinically Considered. By the late CECIL H. LEAF, M.A., M.B. Cantab., F.R.C.S. Eng., Surgeon to the Cancer Hospital. London: Constable and Company, Limited. 1912. Pp. 154. Price 10*s.* 6*d.*

THIS work was left almost complete by the author at the time of his early death, and all who read it will appreciate how great a loss surgery sustained by such an untimely end. Mr. Cecil Rowntree has seen the book through the press, and he has completed the last chapter, which had been left unfinished. The object of the author in writing the book was, he tells us, to record the results of his operations for cancer of the breast, and he took great pains to follow all his cases, so as to obtain accurate information as to their condition for several years after the operation. The anatomy of the breast and the neighbouring structures is fully described. The etiology and the diagnosis are discussed, and then the selection of patients for operation and the choice of the operation performed in each are considered, and the radical operation is described. A chapter worthy of special mention is that in which the results of the author's operations are described and discussed. Dr. T. Johnston English has added a chapter on the subject of anæsthetics.

In addition to a number of black-and-white illustrations there are some very good water-colour sketches by the author, which have been excellently reproduced. The book is a useful clinical study of the disease and of the operations performed for its removal.

LIBRARY TABLE.

The Origin of Life: Being an Account of Experiments with Certain Superheated Saline Solutions in Hermetically-sealed Vessels. By H. CHARLTON BASTIAN, M.D. Lond., F.R.S. Second edition, with an important appendix and two additional plates. London: Watts and Co. 1913. Pp. 98. Price 3*s.* 6*d.* net.—The second edition is in every respect like the first, which was reviewed in THE LANCET of April 29th, 1911, p. 1140, save that an appendix of 21 pages and two plates have been added. The appendix consists of a paper read before the Royal Society of Medicine in November, 1912. The author restates his position as to the nature of the problem and the extent to which, in his opinion, it has been solved, gives replies to criticisms, cites new experiments, and what should be done in further trials. We cannot find that the author has, by his experiments on grapes, or by his additional 280 experiments, added anything to help convince us of the demonstrable accuracy of the position he maintains. We are told that several learned gentlemen, whose names are given, well known in the medical world, "all saw typical budding torulæ which had been removed from one or more of the tubes"—the tubes containing one of the ordinary colourless solutions. We have no independent report by these onlookers. To our mind the position is quite unchanged, and we ourselves still remain unconvinced, save, of course, of the courage and good faith of Dr. Bastian.

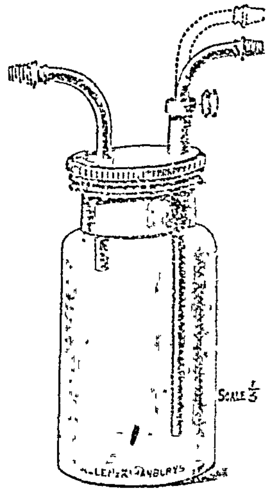
A Manual of Infectious Diseases occurring in Schools. By H. G. ARMSTRONG, M.R.C.S. Eng., L.S.A., and J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxon. Bristol: John Wright and Sons, Limited. 1912. Pp. 155. Price 3*s.* net.—This book is designed to be of service to the masters and mistresses of schools, and the diagnosis and treatment of disease are treated therefore from this standpoint. The infectious fevers that occur in schools are well described, and there is a good chapter on eye infections and one on ringworm. This latter might be read with profit by medical men, many of whom do not apparently realise the urgency, from the school point of view, of accurate diagnosis in this disease. It is unfortunate that in a book the special chapters of which are so thorough the introductory chapter should give the impression of being inadequately considered. This portion of the book is too much dominated by the conception of the mode of disease production found in diphtheria, and unfortunately perpetuates what can be described only as the superstition that burning sulphur in a sealed room is an effective disinfectant. In the treatment of diphtheria also no attention is devoted to possible local treatment and to medicinal treatment; these aids cannot safely be neglected. But these are minor blemishes on a book that well describes the chief signs and symptoms of the infectious fevers, including the typical rashes. The outlines of treatment given are also eminently useful, and are simplified to a degree which should make the subject readily comprehensible to the lay mind. Mr. Armstrong directs attention to the value of croton oil applications for small patches of ringworm, by means of which he "can get the place well more quickly than by X rays."

Digestion and Diet. By THOMAS DUTTON, M.D. Dunelm., M.R.C.P. Edin. London: The Walter Scott Publishing Co. 1913. Pp. 131. Price 2*s.* net.—The fact that this is the fourth edition seems to indicate that there is some demand for such a production. The title is misleading, as there is nothing said about digestion and very little about diet in the ordinary usage of the word. The subject-matter is almost confined to the varieties and sources of foods, and is treated in a very broad, gossipy manner. It is a pity this new edition is not pruned of verbal errors and numerous examples of careless phraseology.

New Inventions.

MEDICATED OXYGEN BOTTLE.

IT is not unfrequently desirable to administer nitrite of amyl, or iodide of ethyl, along with oxygen to patients suffering from anginal attacks or spasmodic asthma. This is usually done by putting the medicament upon a piece of blotting-paper or cotton-wool in the funnel or inhaler close to the patient's face. The inconvenience of this is that the apparatus is apt to move from its position and there is no means of regulating the strength of the inhalation. To obviate these inconveniences a bottle has been made for me by Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W., with two metal tubes arranged similarly to those of an ordinary Woulfe's bottle. One of these, however, can be moved up and down, and may be fastened by means of a screw, as shown in the illustration. The cotton-wool or blotting-paper, moistened with nitrite or iodide, is placed in the bottle. At first the movable tube is drawn well up, so that as the oxygen passes through it over the wool the vapour is dilute. As the nitrite evaporates the tube is pushed further down so as to go closer to the paper or wool, and thus a stronger vapour is obtained. When it is desired to give a diffusible stimulant ether may be employed in a similar way, or a quantity of rectified spirit, brandy, or whisky may be poured into the lower part of the flask and oxygen allowed to bubble through it. The bottle may also be used simply to render the oxygen warm and moist. In this latter case the bottle is half filled with hot water and placed in a small basin of hot water, or surrounded by hot wet flannels. In some cases of bronchitis it may be advisable to add to the hot water friar's balsam, terebene, or other terebinthine preparation.



LAUDER BRUNTON, M.D. Edin., F.R.S.

Stratford-place, W.

THE LANCET.

LONDON: SATURDAY, APRIL 5, 1913.

The Working of the National Insurance Act.

WE have during the last month[1] been publishing the notes of a member of the staff of THE LANCET who, in the character of a Special Commissioner, has been making personal inquiries in certain selected centres of the country into the working of the National Insurance Act with reference to the administration of medical benefit. The area that would have to be covered to make any such inquiry thorough would be the area of Great Britain, for it is a fact that the results of the Act, both as regards the medical service which the country will derive from it and as regards the advantages or disadvantages which will accrue from it to the medical practitioner, will vary greatly in different localities. It is perfectly certain that in many places where identical social conditions appear to prevail, and in many contiguous neighbourhoods, presenting as far as can be seen the same qualities of population, average prosperity, and type of employment, there will be found different responses to the promises of the Act when a close examination is made. It may not be necessary to carry out any such wide scrutiny as is thus suggested, but we propose to continue our investigation of the working of the Act until the main points which have been alluded to in our columns and elsewhere as probably affording material for future amendment have been dealt with. And this is the more necessary as already it is clear that the medical profession as a whole is in two minds about the working of the Act. The number of persons who, whether they approve or not of the almost unlimited extension of contract practice which has now occurred, admit that the material position under the Act is better than they had been led to expect, is on the increase, but there is rightly no relaxation of watchfulness on the part of those who feel that in many ways the sections of the Act dealing with the administration of medical benefits are fraught with danger to medical progress, both scientific and material. The evidence from Scotland, where our representative is next proceeding, will, we believe, be found to bear this out.

Our valuable contemporary the *Manchester Guardian* has made an attempt to survey the working of the National Insurance Act during the first two months, and, according to their summary of the situation, inquiries made in Manchester and Salford go to show that from a purely administrative point of view the defects which were inseparable from the scope of such complex and far-reaching schemes as were inaugurated by the Act are rapidly disappearing. But it is quite clear that the administration of medical and sickness benefits has been attended in Manchester and Salford with the defects which have been mentioned by our representative as occurring in those localities which he has as yet visited. The exact relation of the practitioner who has accepted a place on the panel towards the out-patient department of a hospital, and those who administer it, is difficult to define. Our representative points this out to be particularly so in Carlisle; the author of the articles in the *Manchester Guardian* alludes to the same difficulty in Salford. The hospitals naturally do not consider that an insured person, being in receipt of sick pay, is a proper object for the charity of the hospital when his case is one that could be perfectly well treated by the medical officer to a club on whose list of patients he already figures as an insured person. The medical practitioner on the panel, on the other hand, thinks that the staff officers of hospitals are now finding a great many cases unfit for hospital treatment which before the working of the Act would have received treatment in the out-patient department. And the trouble is complicated by the fact that a certain number of patients being workmen who through various funds collected in their workshops are small subscribers to the hospital do not consider that the benefits of the hospital form in any sense a charity to be withheld from them if they are unsuitable patients for charity. They choose to regard what is done for them at the hospital as a service for which they have paid in their subscriptions, and this attitude which has proved a difficulty already in many places, bids fair to be aggravated.

It was seen when the National Insurance Act first made its appearance as a remarkably unfinished Bill, that many difficulties would centre round such questions as the grant of, and payment for, medical certificates. It was clear that an enormous amount of certification would be required at the hands of the medical profession, while experience warned us that the State would be certain to demand as far as possible that this certification should be done gratuitously. *A fundamentally important point* in connexion with certificates was perceived upon the issue of the Regulations, to be left in a very doubtful position, and this point was raised just before Easter by a suit heard in the King's Bench Division before Mr. Justice BAILHACHE. In this case the plaintiff Mr. W. A. HEARD, a member of a branch of the Ancient Order of Foresters, sought against Mr. C. PICKTHORNE and others representing the Court Abbey Foresters a declaration that a resolution of the society was illegal, *ultra vires*, and unenforcible. The resolution objected to was to the effect that all certificates of incapacity, enabling persons insured under the National Insurance Act in the approved society mentioned to draw sick pay must be signed by medical men on the panel, and that the signature of a medical man not on the panel could not be accepted for the purpose—that is to say, the member of a society who preferred to be attended in sickness by a medical man not on the panel, paying him himself, could not draw sick pay upon the certificate of that medical man, but must obtain one from a member of the panel. Unfortunately, this important point was not decided by Mr. Justice BAILHACHE, who accepted the contention of counsel for the defence, and held that the resolution passed was not, in any event, such an illegal act as to justify an action being brought in connexion with it. It was, he held, a matter to be decided by arbitration under the rules of the society, as contemplated by Section 67 of the Act, with right of appeal to the Insurance Commissioners. Mr. Justice BAILHACHE therefore dismissed the action before him with costs, and any appeal that may be made against his decision will be awaited with interest, as will also be the result of appeal to the Commissioners if the determination of the question should be found to rest ultimately with them.

◆

The Organisation in London of the Treatment of Tuberculosis.

THE practical application of sanatorium benefit was initiated in July of last year, but during the months that have passed since then, although a certain number of patients have been admitted into hospitals or sent to sanatoriums, much confusion has existed in relation to all organised effort to deal with the problem. The London County Council, in its position of central public health authority, is well fitted to systematise the arrangements in London, and we are glad to see that the Public Health Committee of that Council have been requested to prepare forthwith and submit to the Council a scheme for dealing with tuberculosis throughout the Administrative County of London. We have published an account of a report from that committee which foreshadows the course to be recommended. The existing provision for dealing with tuberculosis is in the hands of several authorities and institutions, so that some confusion is perhaps inevitable. These may be classified as follows: (1) official agencies—the County Council, both as a health and an education authority, the local sanitary authorities, the Poor-law authorities (including the Metropolitan Asylums Board), and the Insurance Committee; and (2) voluntary agencies, as the general and special hospitals, the tuberculosis dispensaries, the various nursing, charitable, and philanthropic associations, and religious bodies. It is obvious that if the best results are to be obtained these authorities and institutions must be coördinated. Particularly in relation to the London County Council and the Local Government Board might it be suggested:—

> When two authorities are up,
> Neither supreme, how soon confusion
> May enter 'twixt the gap of both, and take
> The one by the other.

We especially approve of the proposition that advantage should be taken as far as possible of the large general and special hospitals. The advantages they can offer in the way of an experienced staff, beds for observation cases, special departments, and clinical laboratories are far in excess of any provisions that could be made by the local authorities in the shape of new dispensaries, with a limited staff. Important assistance as regards research might also be obtained by investigations made at hospitals devoted to diseases of children, where opportunities arise of studying tuberculosis in the early years of life. This is well illustrated by an interesting paper which we publish this week in another column on the pathology of tuberculosis in infancy and childhood, by Dr. C. PAGET LAPAGE and Dr. WILLIAM MAIR. Further, facilities for research would be much greater and more valuable at one of the existing hospitals than at a newly formed dispensary. In order to facilitate the part to be played by the large hospitals in the general scheme for the treatment of tuberculosis, the staffs of the London special hospitals met on Dec. 10th, 1912, and passed certain resolutions.[1] Among these resolutions one was to the effect that each special hospital for diseases of the chest should be the central tuberculosis authority in its own area; that area would consequently have the advantage of the services of the members of the staff of the hospital and the many opportunities offered by such an institution which we have mentioned, while in an area where no special hospital existed one of the general hospitals could act as the central tuberculosis authority. We heartily commend this proposition and the others passed at the meeting to the favourable consideration of the Public Health Committee of the London County Council.

There is another matter in reference to the working of the sanatorium benefit to which we think attention should be drawn. Tuberculosis officers have been, or are about to be, appointed throughout the country. It is of the utmost importance that care should be taken, first, that they have had an amount of practical experience with tuberculosis sufficient to render them actual experts; secondly, if these officers are appointed by the various local authorities a strict veto should be exercised by the chief administrative body, so as to prevent local influence from being exerted to bring about the election of unsuitable candidates. In order to give those medical men who wish to devote themselves to the duties of a tuberculosis officer opportunities of special study courses of instruction are being instituted at the hospitals for diseases of the chest in London. A complete curriculum should consist of studies in the wards, out-patient rooms and laboratories, instruction in a sanatorium, and in addition attendance on special lectures in the diagnosis and treatment of tuberculosis and in administrative duties. At present the amount of experience required in candidates for these appointments borders on the farcical. Attendance on two afternoons a week at a tuberculosis dispensary over a short period is all that is necessary. We trust that when a central tuberculosis authority is established, at least six months' study in a special hospital will be insisted on. Indeed, we would go further and say that as the duties involved will practically form a special municipal or State service, similar courses of study should be required as in the case of medical officers of health, and certificates stating that the candidates have shown efficiency in this particular branch of medicine should be demanded. We believe that if this plan were instituted, combined with the endowment of laboratories for research, an encouraging commencement would be made for combating the disease. Another advantage resulting from such special training would be that the officers would be in a position to recognise and report upon the rarer forms of pulmonary tuberculosis, and thus add to the general knowledge of that disease. Dr. J. Nicol Galbraith records this week an interesting case of acute tuberculous pneumonia with recovery. This condition is generally supposed to be fatal, but tuberculosis officers will have exceptional opportunities of meeting with similar cases. Especial experience is needed in order to recognise them, but when recognised they may be successfully treated.

◆

Superfluous Oxygen as the Peril of the Mine.

It used to be taught in the early days of chemical lessons that when a candle went out it was safe to assume that the air was no longer fit for human respiration. The belief still prevails even amongst miners, for they reckon that they have had a narrow escape if they eventually reach the surface safely after passing along a mile or so of mine roadway in which the air would not support the combustion of an oil lamp. According to recent researches this is a fallacy, and the observation is of the utmost importance connected with the protection of life in mines. The fact would appear to be that normal air at sea level contains oxygen in excess of the requirements of healthy respiration; and when we reflect that at great altitudes colonies of human beings are known to exist and enjoy a hardy and vigorous life in spite of the fact that the partial pressure of oxygen is only 12 per cent., the point may well arrest our attention. The physique of the Indians dwelling on the upper slopes of the Andes is notoriously splendid, and the inhabitants of the high plateaus of Thibet combine physical vigour with activity. "It is well known," writes Dr. Leonard Hill, "that men can work hard and live vigorous, healthy lives in the mountainous regions of the earth where the partial pressure of oxygen is only 17 per cent. of an atmosphere or less. In the Alps there are noted health resorts at very high altitudes, and the Alpine guides and soldiers are the healthiest of men. Mexico City and Johannesburg were built at an altitude of about 6000 feet. In the Andes railways have been built and mines worked at an altitude of 12,000 to 16,000 feet, and several towns with populations exist at 10,000. The human organism easily compensates itself for the diminution in the partial pressure of oxygen. The ventilation of the lungs and the percentage and total amount of hæmoglobin increase, while the power of the hæmoglobin to hold oxygen in combination also changes, with the result that the tissues obtain an adequate amount of oxygen."

If it can be substantiated that, while chemical combustion requires the presence of something over 17 per cent. of oxygen in the air human respiration can be satisfied with less without any harm accruing to the organism, it follows that a scheme presents itself, the application of which should diminish very considerably the loss of human life in the coal mine. The suggestion of adopting a protective measure based upon these considerations has reached us in a little book written by a practical chemical and mining engineer.[1] He shows that the needs of combustion *and respiration are different equations. Thus in the case* of combustion it is the percentage amount of oxygen that matters, but in respiration it is (within limits) the actual quantity—i.e., the weight in a given volume—that counts. A cubic foot of air, for example, with an oxygen percentage of 17·5, contains, at sea level, almost exactly the same weight of oxygen as an equal volume of air with 21 per cent. of oxygen at an altitude of 5000 feet. A lamp will not burn in *the former, but will, of course, burn quite readily in the* latter. For the purposes of respiration, however, they are *exactly alike. It seems possible, therefore, to provide the* miner with a supply of air perfectly adapted for respiration, but which fails to support combustion. In such an atmosphere he should be able to live a healthy respiratory life, while he should be free from the terrible risks of a fierce chemical union of gases or dust with oxygen which gives rise to the *appalling colliery explosion. While the air is good enough for* him to breathe it would fall short of the requirements of chemical combustion. Dr. Harger points out that, curiously enough, one gas—methane—which is of such vital importance, because it is the chief explosive constituent, in mines, is fortunately extremely sensitive to lack of oxygen, for the methane flame goes out when the oxygen has been reduced to about 17·5 per cent. Hydrogen and acetylene, however, will continue to burn until the oxygen is reduced to 7·5 per cent. and 9·5 per cent. respectively, but they are rarely if ever constituents of mine air. These observations are again of importance, since it means that the acetylene lamp could be used without risk for illuminating the mine in an atmosphere containing a reduced amount of oxygen, but yet which is sufficient for respiratory purposes.

Paradoxical as it may appear, it is quite conceivable that many of the great mine explosions have been caused by the enforcement of a high degree of chemical purity of the air. When ventilation was bad there were, at all events, no great dust explosions, and yet the Coal Mines Regulations Acts insist that a place shall not be in a fit state for working or passing therein if the air contains less than 19 per cent. of oxygen or more than 1·25 per cent. of carbon dioxide. On the other hand, Dr. Leonard Hill has declared that if the mine were ventilated with air containing 17 per cent. of oxygen in sufficient volume to keep the miners cool and fresh, not only would explosions be guarded against, but the mines could be safely worked and illuminated with electricity, and miners' nystagmus prevented. If these conclusions have a good foundation—and they appear to rest on sound reasoning, practical considerations, and experiment—it may well be asked why in the name of humanity the *principles laid* down are not put immediately into practice? Dr. Harger says the reduction of the percentage of oxygen in the ventilating current is undoubtedly the surest method of rendering mines safe from both gas explosions and dust explosions, as well as from the more frequent though less disastrous fires in the roadways, and he adds that this method, founded on his work and only recently discovered, is not yet in practice, though it has been proved that it can be worked *on a large scale* with every satisfaction. Is there any reason for delaying the application of a method which suggests the prevention of an appalling sacrifice of human life and of much human misery and pain?

Annotations.

"Ne quid nimis."

VENTRAL FIXATION OF THE UTERUS.

AN interesting and important discussion on ventral fixation, including under this term the various operations which have been devised of recent years for replacing the displaced uterus and fixing it in a more or less normal position, has recently taken place in the Obstetrical and Gynæcological Section of the Royal Society of Medicine.[1] The term ventral fixation is rather inaccurately used by many writers. It should be reserved strictly for those cases in which some portion of the anterior surface of the uterus is attached firmly by sutures to the structures of the anterior abdominal wall, most commonly to the peritoneum or to the peritoneum and muscle. Ventral suspension, on the other hand, should be employed to mean an operation in which the peritoneal covering of the uterus, either of the anterior or posterior surface, is attached to the peritoneum of the abdominal wall, so that a comparatively loose union or even ultimately a peritoneal band may result. If we may judge by the large number of cases recorded by some of those who took part in this discussion, these operations are performed by certain gynæcologists very frequently. There is, indeed, so great a discrepancy between the number of patients the advocates of these operations appear to see in whom such assistance is required and the number of patients in whom other surgeons find these operations called for, that the impartial critic cannot avoid coming to the conclusion that these procedures are performed by some gynæcologists on very slight indications. Indeed, one speaker rather aptly compared the more fervent advocates of the operation to the mid-Victorian practitioners, who considered all displacements of the uterus of the utmost clinical importance. It is not necessary for us to call attention to the fact, insisted upon by all modern teachers of gynæcology, that a displacement of the uterus *per se* is often of no moment at all, and, indeed, that such a position of the uterus may be normal for that particular patient. It is not an uncommon occurrence to find accidentally a retroversion of the uterus in a young single woman, no doubt congenital in origin, with no symptoms at all, requiring no treatment, and becoming cured as the result of the supervention of a pregnancy. In his remarks on the indications for these operations Dr. W. S. A. Griffith called attention to the two classes of cases in which they might be required, and with his main indications most gynæcologists will cordially agree. For cases of severe prolapse, more particularly after the menopause, in women who have to do hard manual labour, a properly performed ventral fixation, if combined with an efficient strengthening of the pelvic floor—a most important essential—is very successful in relieving the patient and enabling her to dispense with the use of pessaries. With this opinion most of the speakers were agreed, but there was evidently a good deal of difference of opinion as to the necessity for the operation in case of mobile backward displacements, and as to the success attending it. It has been pointed out by many writers that a large number of cases of backward displacements of the uterus, more particularly when combined with prolapsed and painful ovaries, are associated with a marked degree of neurasthenia and failure of the patient's general health. The latter condition is, indeed, often the actual or, at any rate, an aggravating factor in the production of the pain, and the general nervous state of the patient may be rendered much worse by mental worry and distress consequent upon the presence of dyspareunia. It is not to be wondered at, then, that in this class of case the woman is often but little benefited, and that the operation does not cure all the neurotic manifestations which she exhibits. In many instances the best cure for this state of things is a pregnancy, but not infrequently the mental distress is still further aggravated by sterility, and when all other remedies fail there is a great temptation to resort to one or other of these surgical procedures. The exact part played by the operation in giving relief in such cases is difficult to measure, and it is a not infrequent experience to find that when the effect of the rest in bed and the part played by suggestion has worn off the pain and symptoms return. We willingly admit that in many such cases great relief results and even pregnancy may occur and complete the cure, but it is in this class of case, where the main complaint is pain, that the ultimate results are so difficult to gauge and in which the records of individual observers are so likely to be unintentionally misleading. That the operation is an unscientific one is not in our opinion an argument of much weight; medicine is not an exact science, and many of the methods we employ with success for the relief of our patients are far from being scientific. To fix an organ which should be capable of movement may indeed be called unscientific, but if such a procedure cures a patient of symptoms which cannot be cured by any other means then the objection that the method is unscientific is of no value. That cases of intestinal obstruction may follow, and have followed, such operations is no doubt true, but this objection, when we remember the very small percentage of cases in which such an accident has occurred, is but a very minor one, and can be avoided by proper technique. There must of necessity in every operative undertaking be a certain small risk, but so long as the surgeon has faithfully and truthfully pointed out to the patient that such a risk exists, then provided that the patient with such knowledge is prepared to run the risk, it cannot be allowed to weigh too much against any procedure. The operations for fixing the uterus call for little skill, are attended with but a slight risk, and therefore lend themselves to abuse by those practitioners who take too narrow a view of their responsibilities, and who do not weigh with due care the value of the different symptoms present in each individual case. We have always thought that the best test of the legitimacy, if we may so term it, and necessity for any operation is the relative frequency with which it is performed by the surgeons attached to a large general hospital with a medical school—that is, in those conditions in which competent and honest criticism is not likely to be lacking. Judged by this standard, these operations of ventral fixation certainly appear to us to be justifiable in a certain selected number of cases and in certain very definite conditions, but hardly appear to be necessary to the very large extent to which they are practised at the present time by some surgeons and gynæcologists.

THE FORTHCOMING IMPERIAL SERVICES EXHIBITION.

PROBABLY no more fitting subject at the present time could have been forthcoming for the Earl's Court Exhibition of 1913 than the Imperial Services. Since the last Naval Exhibition of 1891 and the last Military Exhibition of 1890, both of which were held at Chelsea, Great Britain has passed through one serious war and has stood on the verge of other wars, while the struggle now in progress must result in a momentous change in the map of Europe, compelling all nations to consider their offensive and defensive positions.

---

[1] THE LANCET, March 29th, 1913, p. 888.

Apart from the interest to every patriotic citizen of all things relating to the security and defence of his country, both by sea and land, the medical profession has a twofold link with the army and navy. Not only is there a specialised military medicine, necessitating the existence of a special corps of military medical officers—using the term "military" in its generic sense, to cover both the navy and the army—but also to that corps is due a large measure of additions to the common scientific knowledge of the profession, more particularly in the domains of tropical medicine and hygiene and of the surgery of wounds. The exhibition will naturally include much that is of great interest to all medical men in relation to ambulance and surgery. The Red Cross Hospital will be utilised for displays of a specialised training of civilians to fit them to cope with emergencies and the disasters of civil life in the mass, as well as with individual first aid. In recent years we have had the eruption of Mont Pelée and the destruction of Messina as examples of the kind of catastrophe that makes the whole world shudder; and even as we write we realise that across the Atlantic there is at this moment another dramatic contest between man and the elemental forces of nature. It is in times such as these that we recognise the need for trained and organised help—a need as great in this strife of civil life as any need of war. That the medical aspect will not be neglected we may judge from the presence on the committee of Surgeon-General Sir James Porter, the head of the Navy Medical Department, Surgeon-General Sir Launcelot Gubbins, the head of the Army Medical Department, and Sir Arthur Conan Doyle, whose experience in South Africa makes him a fitting representative of what may be regarded as the civilian auxiliary to the official medical services. A still further claim of the exhibition for support lies in the fact that, should any profits accrue, the service charities will benefit thereby.

BACTERIOLOGY FOR PHARMACISTS.

THE revision of the syllabus of the pharmaceutical examinations must before long receive attention, and it is perhaps possible to obtain some idea of what is contemplated by the Council of the Pharmaceutical Society from the fact that under its auspices the last of a series of lectures on bacteriology has just been delivered in the lecture theatre of the School of Pharmacy by Professor R. T. Hewlett, of King's College. A knowledge of bacteriology would undoubtedly be a useful acquisition to pharmacists, although it is hardly an essential part of the equipment of the average chemist and druggist. If this be the view of the Pharmaceutical Council, the subject of bacteriology is more likely to be introduced into the syllabus of the higher or "major" examination than into that of the qualifying or "minor" examination, which latter is, for the present, considered by most pharmacists to be a sufficiently severe test. In his final lecture Professor Hewlett outlined a course of instruction in microbiology, pathological chemistry, and microscopy, which he considered might be advantageously introduced into the pharmaceutical curriculum. This included the principles of sterilisation and the preparation of culture media; the effects of the development of bacteria on certain pharmacopœial preparations, and the means of preserving such preparations; the principles of antiseptic and aseptic treatment, and the preparation and use of curative sera. He estimated that an elementary course of this kind would require as a minimum some 20 lectures of three hours each, provided the students possessed some previous biological training and a knowledge of the use of the microscope. As the pharmaceutical student's acquaintance with biology is of a very meagre kind, the 60 hours suggested would hardly suffice unless a modification of the present course in botany were made, diminishing the amount of systematic botany required, and making the course not a course in botany only, but altering it to one in general biology, including animal forms as well as vegetable ones, somewhat on the lines of the old syllabus in biology of the Preliminary Scientific (M.B). Examination of the University of London. For advanced students Professor Hewlett suggested a further course of instruction such as would put the pharmacist in a position to assist medical practitioners in the diagnosis of disease by undertaking the investigation of morbid material. Provided such work entailed no encroachment upon the functions of the medical practitioner, there seems to be a place for pharmacists who are trained to undertake investigations of this kind, but an increasing number of medical men happen at this time to be working in the same direction. The duty of the pharmacist to whom such work was entrusted would be, as Professor Hewlett pointed out, merely to report on his findings and not to attempt to make any deductions therefrom.

POISONING BY PETROL FUMES.

THE danger due to the highly inflammable nature of petrol fumes is well known, but not the danger due to their toxic properties, as very few cases of poisoning have been recorded. In the *Canadian Medical Association Journal* for February Dr. Guy W. Johnson has reported 42 cases of poisoning which occurred in the construction of the Montreal tunnel. This tunnel is about 650 feet long, 8 feet high, and 12 feet wide. Ventilation was carried out by a zinc pipe 8 inches in diameter, through which air was forced in by a fan, and also by the compressed air used to run the drills. A petrol motor engine was employed to draw the cars of rock from the face of the tunnel to the bottom of the shaft. As long as the engine was not running the ventilation was sufficient to keep the air in the tunnel fresh, except for a few minutes after blasting. But within an hour after the engine was started the air became foul, causing throbbing and congestion of the vessels of the head and headache. On Nov. 22nd two men were overcome by the fumes from the engine and carried out. They suddenly collapsed and became unconscious. Dr. Johnson saw them within 20 minutes, when they were recovering. The most notable feature was extreme flushing of the face. The pulse was 100 to 108 and of good volume and tension. Respiration was 46 and deep. The knee-jerks and the plantar and cremasteric reflexes were absent, but the conjunctival reflex and the pupillary reaction to light were present. The pupils were moderately dilated. The men could move their arms and legs but could not speak. There was slight salivation. Consciousness was rapidly regained, but the men complained of severe headache, chiefly frontal. They returned to work in about an hour, and next day were none the worse for their experience. On Nov. 24th 16 men suddenly collapsed within a few minutes of one another without any warning. They were brought to the surface as quickly as possible and seen by Dr. Johnson within 20 minutes of the occurrence. They were in all stages of anæsthesia; some had recovered consciousness and showed only headache, muscular weakness, and salivation; others were shouting and struggling as in the second stage of ether anæsthesia. A few were unconscious, with complete muscular relaxation. In two there were also clonic spasms of the arms and legs, which came on every few minutes and lasted about a minute. All the men also showed the symptoms described in the previous two cases. On the next day they were able to work, but 18 men were overcome in the same way. Spectroscopic examination of the blood revealed absence of carbon monoxide. Analysis of the air in the tunnel showed traces of petrol fumes and no carbon monoxide. Four rats were placed in separate bell-jars into which a little petrol was introduced. They showed the following symptoms: first, reddening of the noses and gums; secondly, salivation; thirdly, restlessness; and fourthly, muscular relaxation and anæsthesia, which came on in 1½ to 2 minutes. A stage of clonic spasms, with relaxation between the spasms, followed. The rats were then removed and recovered in about 30 minutes, but three died without apparent cause next day. Post mortem their livers seemed very friable. Two fox-terriers were anæsthetised by inhalation of petrol with similar symptoms. After 15 minutes of anæsthesia the circulation and respiration ceased simultaneously without warning, and resuscitation could not be performed by any means. At the necropsy the heart was found to have stopped in diastole, and the right side was dilated. The veins all over the body were much distended. There was marked congestion of the liver and of the posterior parts of the lung. Thus, the toxic symptoms in man and in the lower animals are very similar. A noteworthy point is that the conjunctival reflex does not disappear and that the pulse is good and not very rapid. After the stage of muscular relaxation there are clonic spasms, which Dr. Johnson regards as a danger signal. Dr. C. R. Box has described two cases of petrol poisoning in chauffeurs who were manœuvring a motor-car about a closed garage.[1] He noted that in one case the face was flushed and cyanosed and in the other pale. In both there were muscular weakness, shivering, and spasms, but no vomiting. The pulse was rather small and fast, thus differing from Dr. Johnson's cases. Mr. M. J. Houghton has reported the case of a woman who was overcome in three minutes while washing her head with petrol in a small bathroom.[2] When seen 15 minutes later she was of an ashy-grey colour. The conjunctivæ were slightly suffused, the pupils dilated, and the lips slightly cyanosed. The pulse was 90 and thready. Dr. Fraser Gurd has, in a personal communication to Dr. Johnson, described a necropsy on a man who was found dead in a large tank which he had been cleaning with petrol. Nothing was discovered but venous congestion.

SOME INSANITARY FEATURES OF THE EXTEMPORISED PICTURE THEATRE.

THE extraordinary popularity of cinematograph exhibitions has led to the acquisition of scores, even hundreds, of buildings in which to give the demonstrations. The entertainment is perfectly wholesome and gives a cheap form of amusement and instruction to large crowds. But the evidence is plain on all sides that the buildings are not always wholesome. The cinematograph theatre is often a Black Hole of Calcutta, with no provision for ventilation at all. Especially is this the case with the extemporised theatre. Almost any old shop, in place of waiting for a trade tenant, can be adapted for the purpose of a cinematograph show, and there are many such shops in the metropolis, and doubtless in the provinces also. When a building is specially designed and ultimately constructed for the purpose we may fairly assume that the provisions for ventilation laid down by our health authorities for new buildings are followed. Whether, however, the place is a new building or an adaptation of an old shop, it is an essential of the performance to keep the actual theatre dark. The two factors of health, light and fresh air, can therefore seldom be contemporaneous even in the buildings specially designed for the purpose, while it is obvious in the case of certain of the abandoned shops which have been adapted for these exhibitions that both light and fresh air are excluded. The condition of some of these dark and unventilated enclosures is a grave comment on our modern views of what is healthy environment, and the enormous patronage which the picture theatre receives indicates how widespread may be the effects of an unhealthy stay within its walls. Evidence has been produced which suggests that such places have been a means of spreading infectious diseases particularly amongst children. Our sanitary authorities would do well to give their special attention to this matter, and initiate steps to ensure the people taking their recreation and instruction under physical surroundings that admit of no hygienic reproach.

PHLEBITIS IN MUMPS.

THE usual conception of mumps as a transient inflammation of the parotid glands attended with slight constitutional disturbance can no longer be held. Observations in recent years, principally by French clinicians, have shown that the disease may, like other infections, be attended by grave complications, such as pancreatitis, meningitis, neuritis, endocarditis, and pericarditis. For example, at a meeting of the Société Médicale des Hôpitaux of Paris M. E. Hirtz and M. Salomon reported a complication of mumps which does not appear to have previously been noticed—phlebitis. Of this they observed three cases in one household, the patients being a medical man, his wife, and his sister. The former was attacked while attending several members of a family for mumps. There was intense inflammation of the right parotid gland, and the temperature rose to 101·5° F., but fell to normal on the following days and the parotitis rapidly diminished. On the seventh day he had a rigor and the temperature rose again to 101·5°. On the eighth and ninth days it oscillated between 102·5° and 102·7° and was accompanied by malaise. On the tenth day it fell to 100·7°, but pain was felt in the right calf. On the eleventh day the temperature was again normal, but the pain persisted, compelling the patient to remain completely at rest. Examination on the fourteenth day showed a red line in the course of the internal saphenous vein, which was tender. The limb was not œdematous. On the fifteenth and sixteenth days the temperature was normal, but on the eighteenth it rose to 100°, and the femoral vein became painful. There was slight œdema over the malleoli. The limb was immobilised in a splint. The left lower limb now became painful, and acutely so in the calf. The whole of the course of the external saphenous vein was tender to the slightest touch. Recovery slowly took place under massage, electricity, and mechanical therapeutics. The patient was not able to walk normally for nearly four months. His wife, who nursed him, was seized at the time of a menstrual period with pains in the breasts and in the position of the ovaries. She also had sensation of weight in the legs. The pains increased so much that she had to take to bed. She then remarked that for some days the parotid regions were a little tender, and there was some difficulty in mastication. In the position of the right femoral, the two right saphenous, and the left saphenous veins there was marked pain. On palpation of the right iliac fossa a painful swelling was felt in the position of the right ovary. Ovaritis and phlebitis, due to mumps, were diagnosed, and the lower limbs were immobilised. The temperature did not rise above 99·3°. The affected veins formed hard cords and there was some œdema of the legs. On the nineteenth day there was intense pain in the left arm, which was attributed to neuritis due to mumps. Recovery slowly took place under the same treatment as in the previous case. The practitioner's sister, a married woman, was attacked with mumps Her temperature rose to 104° and there was acute pain in the ovarian regions She slowly recovered and remained pale and wasted About two months after the onset she went to the seaside, but after a few days had to take to bed Her temperature rose to 104 7° and there were rigors The temperature remained elevated for 10 days and then gradually fell She complained of pain in the left leg, which was œdematous The internal saphenous and the femoral veins became painful, and phlebitis was diagnosed She was not able to get up until the fifteenth day of the disease It is noteworthy that in the first two cases the phlebitis appeared about a week after the parotitis, while in the third case it did not appear until two months after All the patients were run down when they contracted the disease, which partly explained its intensity and tenacity, but the infecting microbe also appeared to be unusually virulent These cases are not completely novel M Hirtz and M Salomon have been informed by Dr Henri Béclere of a case of phlebitis in mumps observed by him And in the *Statistique Medicale de l Armée* for 1906 they found recorded the case of a soldier admitted to hospital for orchitis, which in consequence of an outbreak of mumps in the regiment at the time was attributed to this cause After the temperature became normal he complained of slight pain in the right thigh, and the temperature rose again While sitting up in bed he died suddenly The necropsy showed phlebitis of the veins of the spermatic cord and of the epigastric vein

THE CHARACTER OF BENVENUTO CELLINI[1]

THE character of Cellini as disclosed in his autobiography, has ever afforded both pleasure and food for thought to psychologists The *Vita* has been criticised before, notably by Baretti, Bacci, Renier, and Paul Courbon Dr Querenghi associates himself in the main with the theory that Benvenuto Cellini inherited a nervous temperament from parents who were advanced in age at the time of his birth, that this morbid predisposition was exaggerated by the malaria syphilis, and plague from which he was known to have suffered, that his unstable mental equilibrium was shown in his criminal impulses, obsessions, absence of moral sense ideas of persecution and grandeur, and in sexual perversion Dr Querenghi is, however, at pains to disprove the accusation of homosexuality, and we think he fairly succeeds as far as the evidence in the *Vita* enables him to do so That Cellini mismanaged *and muddled his affairs is evidenced by what took* place when his celebrated "Perseus" was cast He made his furnace of pine instead of oak, nearly burned down the shed where the metal was being fused, and so miscalculated the quantity required that if he had not at the last moment thrown in his pewter pots and pans the statue would have come out headless! Dr Querenghi finds Cellini wanting in artistic perception, as shown by his criticism of his contemporaries Donatello and Bandinelli and he considers that as an artist he compares unfavourably with them, an opinion he seeks to maintain by contrasting his work with theirs This view, however, will probably not be shared by the majority of artists Evidently Cellini was utterly tactless He preferred to go out of his way to alienate his patrons and their wives, notably Pope Clement VII, the Duchess d'Etampes and Eleonora da Toledo, wife of Cosimo I In these transactions the artist appears in not a very creditable light and throws the blame on bad luck instead of his own psychological deficiency *Another characteristic of* Cellini s degeneracy is that he was "vindictive as a viper," as Baretti says, and quarrelled with almost all his friends According to Dr Querenghi the key to Cellini s mentality is to be found in self delusion, by which he exaggerated his own condition and every aspect of his life, for example, his statement of having vomited a worm a foot long, whereas the probability is that it was a small caterpillar he had swallowed with some water The alleged attempts to poison him and his fight with Gherardi come under the same category. In fact, megalomania is manifest even in the first lines of his *Vita* in which he talks of the *obligation* resting on "men who have at least done something praiseworthy" to write their own biography, an obligation which was neither felt nor entertained by his more celebrated predecessors and contemporaries in the realm of art As a result, while Cellini put down the truth as he felt it, he unconsciously drifted further away from the actual truth the more the fantastic element was present Dr Querenghi draws a comparison between Cellini and Don Quixote, and opines that if the Spanish knight had really existed and written his autobiography we should have had another *Vita* like that of Cellini This is a piece of literary criticism which strikes us as a little surprising

THE OYSTER SUPPLY.

SOME interesting facts connected with the oyster industry were brought forward at the annual general meeting of the Oyster Merchants and Planters' Association, held in the Fishmongers' Hall on March 31st It will be learnt with some dismay by the oyster consuming public that the supply of natives grows shorter year by year, and unless purely empirical methods of cultivation are soon given up in favour of scientific treatment the gourmet's favourite may disappear This is a regrettable fact and it is to be hoped that funds will soon be forthcoming and that Government help will be given in order that a comprehensive scheme of research into the conditions which affect the spatting, growth, and fattening of the oyster may soon be proceeded with The question has been taken up in France in a thoroughgoing spirit, with the result that the oyster industry there has been practically rehabilitated The matter is of considerable public importance, since the shell fish industry of the United Kingdom represents an estimated capital value round the coast of from six to eight millions, which gives employment to a large number of men and supplies a dietetic delicacy which many would be sorry to lose Another menace to the prosperity of the industry is the alarming increase of American or "slipper" limpets, particularly in the Thames estuary, which "spat" upon the oyster grounds and consume much of the food that otherwise would go towards "fattening' the native To some extent this mischief is being reduced by giving rewards to dredgerman who bring "limpets, five fingers and mussels, and other vermin ashore for hard way making and other purposes " The industry, assisted by the Fishmongers' Company, has worked hard during recent years to remove the reproach against the oyster as a source of enteric disease, and great efforts have been made to keep all beds clean and free from sewage polluted water. Excellent progress has been achieved, with the result that public confidence has been largely restored The great mass of oysters now comes from beds of certified purity, but the system of inspection needs widening The Oyster Merchants and Planters' Association has requested the Board of Agriculture and Fisheries and the Local Government Board to see that no time be wasted in getting through a rivers pollution Bill which shall safeguard the public and protect the interests of the industry They accept the recommendations of the Royal Commission on Sewage Disposal, which provided that control in all questions affecting our rivers and estuaries should be vested in river boards, with a controlling authority with power to take action to prevent the pollution of the waters. In short, the attitude of the shell-fish industry in regard to sanitary considerations is admirable, and it would be a great misfortune, now that the importance of these considerations is being realised and acted upon, if the prosperity of the industry should suffer through the neglect to make a systematic scientific study of the conditions under which the best oyster can be produced and the yield increased. There are few persons, we imagine, who do not want the supply of oysters to be pure, plentiful, and cheap. They are a valuable food.

TREATMENT OF TYPHOID FEVER BY TINCTURE OF IODINE.

IN the *Journal de Médecine et de Chirurgie Pratiques* for Jan. 25th of this year is an article dealing with the treatment of typhoid fever by tincture of iodine. Although the therapeutic use of iodine in this disease was suggested as far back as 1859, and reference has been directed to the matter since, notably by Dr. David Walsh in 1907, no extensive trial seems to have been made of this method. Nevertheless some observers have claimed successful results, and further trials would certainly seem desirable. Treatment based on bacteriological observations has of recent years attracted so much attention that the employment of drugs has not been so fully investigated. Dr. G. Perez has written to the above-named journal urging that the time has arrived to put this method to an extensive practical test. The employment of drugs possessing antiseptic properties has not met with great success in the treatment of typhoid fever, but it has been suggested that tincture of iodine is not only antiseptic in its action, but helps to clean the ulcers and to hasten their cicatrisation. Its use, therefore, in typhoid fever would on these grounds be indicated. In the article to which we have referred the addition of pyramidon is recommended as an antipyretic in order to replace the employment of baths for bringing down the temperature. If a good effect could be produced with the drug it would be of advantage where the use of baths is difficult. The true value of these therapeutic measures can, however, only be estimated by extensive practical experience.

THE TRANSMISSION OF SLEEPING SICKNESS BY MORE THAN ONE SPECIES OF TSETSE FLY.

EXPERIMENTAL investigations have proved that under certain conditions Glossina morsitans as well as G. palpalis can act as the insect transmitter of sleeping sickness infection. Kinghorn and Yorke in Rhodesia have shown also that not only is G. morsitans the conveyer of the disease, but also that the particular parasite of sleeping sickness in that region is T. rhodesiense, and not T. gambiense. Rodhain and others have demonstrated that G. morsitans in the absence of G. palpalis spreads the infection of sleeping sickness in Southern Katanga. As a result, some experts now lean to the conclusion that under certain circumstances various species of glossina may probably be able to transmit various species of trypanosomes; and that possibly the individual trypanosome species are not invariably associated with individual species of glossina. Another series of experiments relating to this question has recently been reported in the *Archiv fur Schiffs- und Tropen-Hygiene* for February, by Staff-Surgeon W. Fischer, of the German East African Protectorate Forces, who sought to discover if, at the altitude of the Victoria Nyanza, 4000 feet above sea level, the infection of T. gambiense could be conveyed by G. morsitans as well as by G. palpalis. For this purpose he fed G. morsitans, in groups of 100 each, on 14 infected monkeys for four days; the flies were then allowed to fast for two days, after which from the seventh to the seventieth day they were fed each day on a new healthy monkey. In 12 of the experiments the results were negative; but in two they were positive, the monkeys becoming infected. Each of the 1400 flies employed in the experiments was carefully examined after death. Three only were found to be infective, with completely developed trypanosomes in their intestines, and these had been the agents in conveying the infection to the monkeys. Twenty other flies, however, had developing trypanosomes in their gut. From these experiments it is permissible to infer that in the Victoria Nyanza region G. morsitans as well as G. palpalis can act as the vector of sleeping sickness infection.

CHRONIC MANGANESE POISONING.

IN the *Journal of the American Medical Association* of March 1st Dr. Louis Casamajor contributes a preliminary account of a syndrome which he ascribes to chronic industrial intoxication by manganese. He has seen nine patients, workers in the separating mill of a large mine, the chief product of which is zinc. Throughout this mill the air is laden with a fine grey dust, consisting of ore which contains zinc and manganese, with a negligible fraction of lead. The symptoms, which are ascribed by Dr. Casamajor to absorption of manganese through the alimentary tract, are somewhat like those of paralysis agitans; there is a similar disturbance of gait, which the patient first discovers as an inability to walk downhill slowly. The mask-like expression of face has also been noticed; the legs feel weak and shaky, there is a fine static tremor of the hands and tongue, but muscular power is well preserved and the reflexes are unaltered. There are no sensory changes, apart from deafness which is not aural in origin, and the mind shows no definite evidence of deterioration. It is the gait that is most profoundly affected, and it is noteworthy that retropulsion occurs as well as propulsion; the patient cannot walk backward, for as soon as he tries to do so he falls backward or sits down. There are no blood changes, the cerebro-spinal fluid is normal, and the Wassermann test is negative. In the urine distinct traces of zinc and manganese have been discovered. Dr. Casamajor gives reasons for attributing the symptoms to poisoning by manganese and not zinc. One of these is that zinc has never been proved responsible for systemic poisoning, and the other, that certain cases of a closely similar type have been reported among other manganese workers. He promises a fuller account of his investigations, including a record of post-mortem findings, and the subject should prove important and interesting, since it promises to add one more to the ever lengthening list of preventable diseases.

THE appointment of Mr. James Devon, L.R.C.P. & S. Edin., L.F.P.S. Glasg., as Prison Commissioner for Scotland, in place of the late Mr. T. D. M. T. Robertson, has been approved by the King.

THE BIRMINGHAM MEDICAL INSTITUTE.—The annual meeting of the members of this association was held on Thursday, March 27th, Mr. Gilbert Barling, President, in the chair. The report of the committee showed a balance on the revenue account of £56 6*s.* 4*d.* in favour of the institute at the end of 1912. In response to an appeal from the president at the previous annual meeting, the sum of £502 12*s.* had been contributed to a fund for increasing the capital of the institute, and further donations to the amount of £106 15*s.* had been promised. It was pointed out that additional support is urgently needed. A cordial vote of thanks was passed to the president for his services during the past three years, and the proceedings terminated with the election of the honorary officers for the ensuing year.

MEDICINE AND THE LAW.

Medical Practitioners and Undue Influence

A RECENT action in the Probate Division has reminded us of how easily a medical man benefiting under the will of a deceased patient may be made the subject of a charge of having taken advantage of his position to secure his own profit The charge is an odious one, and once made has to be faced The strict rights of the legatee should be insisted upon, or the accusation will be deemed to have succeeded with implied admission of its truth This was the course pursued in the litigation arising out of the will of Miss Maria Mattingley, in which the jury found, after the briefest possible deliberation, that no undue influence had been used over her by her nephew, Mr Frederick Bryan, a medical practitioner The case is of such a near date that we need only recall its salient points

ome instances
ce that owing
place, and in

which the making of a will is spoken of, if it be discussed at all before the medical adviser, they have not the advantage as a rule of the testimony of others to the effect that the confidence reposed in them has been in no sense abused On the other hand, they are frequently the objects of the suspicion of jealous relatives Mr Bryan had a strong point in his favour in the fact that he was the nephew of the old lady whose dispositions in his favour were disputed Moreover, he was not only a near relative, but had done for her what any near *relative should do and may do without suspicion of* sinister motives in his circumstances Renewing an acquaintance with Miss Mattingley, which had for some time been discontinued, he found her elderly, infirm, and neglected, her house dirty and ill kept, and herself suffering from cancer of the breast He made an end so far as he could of these undesirable conditions, and although the case seems to have been stated against him as if, by constituting himself exclusive *medical adviser to his aunt, he had obtained influence* over her in her business affairs, he was able to call Mr W H Battle and Dr H H Mills, who at different times had seen her at his request, and to rely upon their testimony as to her mental capacity In fact, it was abundantly proved that Mr Bryan had done so much for the testatrix that, taking into account the relationship between them, it was, at any rate, not unnatural or surprising that her most recent will *should more substantially benefit him than one that preceded* it, or than one the making of which was contemplated but not signed

The law in no way forbids a medical practitioner to benefit under the will of his patient He, like other persons, must not have exercised "undue influence"—that is to say, he must not have employed any persuasion or pressure such as would prevent the testator from exercising his judgment in a proper manner, and of course he must not have taken advantage of any mental weakness As a general rule, however, apart from any question of ethics, the influence of a person standing in a fiduciary relation to a testator may lawfully be used to obtain a will or legacy so long as the testator thoroughly understands what he is doing and is a free agent, and of course suspicion must be confirmed by evidence when the general facts surrounding the making of a will are of a suspicious character Suspicion will certainly and justly arise when a will confers large benefits upon the person by whom, or by whose agent, it has been prepared, or when it markedly favours a medical man in whose house the testator was residing when it was made Neither of these two elements, however, was present in Mr Bryan's case, except to the extent that he introduced a solicitor whom he had employed himself, and whom he knew, to make Miss Mattingley's will. That lady undoubtedly asked him to do this, and gave her own instructions personally and privately to the lawyer It is interesting to note that among the well known cases in which the question of undue influence has been discussed with reference to a medical man and his patient is one in which, as in that of Mr Bryan, there was a testatrix who was the aunt of the person benefited, and was also a lady of considerable age In this case, Reece *v* Pressey, decided in 1856, the nephew was the medical attendant of the testatrix and drew up her will himself He took under it the whole of her property except £100, which went to his sister, who disputed the will He was alone with his aunt on the occasions when she discussed her testamentary intentions and wishes with him, so that his evidence as to what took place between them stood alone He stated as to this that his aunt wished him to draft the will so that it gave him everything, and that he refused to do so, suggesting that half the property to be disposed of should go to his sister, with the result that the testatrix yielded to his wishes only so far as to consent to the sister receiving a legacy of £100 There were letters to him from his aunt asking him to come and see her, and referring to business which she wished him to help her to settle, there was evidence also that she was of sound mind, though feeble in body, and eventually the court pronounced in favour of the will, which, of course, was duly signed and witnessed In another case, Jones *v* Godrich, also decided many years ago there was even more occasion to suggest undue influence, for, although the testatrix had no near relatives, she had distant ones in whose favour she had already made a will, and her medical attendant, to whom she left the bulk of her property by the will in dispute, was not related to her Moreover, she resided in his house, and was 86 years of age when she died The will nevertheless was upheld by the court, and it was laid down that in order to invalidate it there must be evidence of undue influence practised with respect to the will itself, or so contemporaneously with the making of it or connected with it as by almost necessary presumption to affect it "Flattery and obsequiousness" were referred to as methods degrading to the person using them, but not in themselves constituting such undue influence on the acts of a capable testatrix

In short, the medical practitioner to whom a bequest is made may become the subject of suspicion, but in order to deprive him of what is otherwise his lawful due a strong case must be made out, as with other legatees occupying positions of confidence with regard to the person whose will is in question It may be shown that influence has been used, but mere influence is not enough It must have been of such a degree *as to have deprived the person making* the will of the proper mastery of his or her faculties Nor do we see any ethical, as distinct from any legal, reason why a medical practitioner should not benefit to a reasonable extent under the will of a patient who may desire to express his gratitude for services rendered upon which he may set a higher value than that represented by fees, paid upon a customary scale We, of course, do not suggest *that "influence" of any kind should be used deliberately* by medical practitioners or by anyone else in order to obtain legacies The idea is repulsive to every honourable and well-balanced mind Each case of alleged influence, however, must depend upon its own facts and circumstances, which differ widely, and however hard it may seem to relatives of a deceased person to be excluded from his will it is as well to remember that not all relatives love one another, *and that the gift to a person who is not related may* be due to this rather than to any other fact A legacy to a friend instead of to a relative may simply take the place of a bequest to a charitable institution which no one could accuse of exercising undue influence Nothing has been said above as to gifts made by a person when alive to his medical attendant, or to any other person whose position of trust brings him under the suspicion of having obtained such *a donation by improper means In general, no medical* man could prudently accept from a patient under his care a present representing a substantial part of the donor's property, we refer to such a gift as in an ordinary case would not be bestowed except after death with all the formalities attendant upon the making and proving of a will At all events, on any such occasion the medical man should put himself beyond the range of suspicion by insisting upon everything being *done under competent legal advice, and in* such a manner as to secure full protection for his patient and for what is not less important in very censorious times, his own credit

Questions Arising under a Partnership Agreement

An action was brought recently in the Chancery Division by Mr W G H M Verdon against Dr R D Bell, medical men practising at Luton, in which the *former sought to test* the validity of a notice served upon him by the latter to dissolve their partnership In opening the case counsel explained that the defendant, the survivor of a partnership, had taken the plaintiff into partnership in 1909, the plaintiff paying to a retiring partner of the defendant a substantial sum in respect of a share in the goodwill of the practice. The articles of partnership stated in some detail conditions under which the plaintiff and defendant should practise together, and the notice referred to gave particulars of alleged breaches of those conditions complained of by the defendant. After counsel for the plaintiff had opened the case as stated, counsel for the defendant intimated that he thought that the matters in dispute might be arranged between the parties if Mr. Justice Warrington would give them and their counsel the opportunity to come together. Accordingly the hearing of the case was adjourned, and upon its being called on again it was announced that a settlement had been arrived at. The terms, so far as they were stated, were to the effect that the partnership should be dissolved, a substantial sum being paid to the plaintiff by the defendant; that an accountant should be called in to settle the accounts of the partnership; and that each partner should be at liberty to practise in Luton, retaining his own patients and any appointments that he might hold. All charges that had been made were withdrawn, and upon the application of counsel an order was made to stay the proceedings.

Action against Original Vendor of Diseased Pork.

In the case of Cointat *v.* T. Myham and Son, recently heard by Mr. Justice Coleridge, the jury found a verdict for the plaintiff in the following circumstances. The tuberculous carcass of a pig was seized by a sanitary inspector on the premises of Mr. Cointat, where it was admittedly exposed for sale as food, and he being convicted was fined £20 under Section 47, subsection 2, of the Public Health (London) Act, 1891. The subsequent action referred to was brought by Mr. Cointat, who had exposed the diseased pork in ignorance that it was unfit for human food, against the firm which had sold the pig's carcass to him for breach of an implied warranty that it was merchantable and reasonably fit for food. The jury found that the meat was unfit for human food, that the plaintiff had impliedly told the defendants for what purpose he was buying it from them, and that he did so in such a way as to show that he relied on their skill and judgment. The damages which the plaintiff claimed consisted, firstly, of the amount of his fine and costs, as to which the jury awarded him £36; and, secondly, were for loss of custom owing to the breach of warranty, as to which the jury awarded £200. Mr. Justice Coleridge delivered a reserved judgment upon these findings, the question being whether the damages under both or either of the two heads indicated were recoverable at law. This involved the consideration of whether they arose naturally out of the breach of the contract and could fairly and reasonably be considered to have been in the contemplation of both parties as the probable result of the breach of the contract at the time of making it. As to the damages arising out of the conviction, his lordship had little difficulty in arriving at the conclusion that they were not too remote. Absence of negligence would have been no defence to the plaintiff when prosecuted and consequently his conviction did not imply negligence on his part. There was no suggestion that the fine had been increased owing to any such negligence. Consequently Mr. Justice Coleridge held that the damages arising directly out of the conviction were recoverable, being within the principle of the leading cases on the subject of damages. (Hadley *v.* Baxendale, 9 Exch. 341; Crage *v.* Fry, 67, J.P. 240.) The question of damages arising from loss of business consequent upon the prosecution required more consideration, but after reviewing the cases upon the subject of remoteness his lordship held that the plaintiff might recover, on the ground that the loss of custom might be taken to have been in the contemplation of the seller at the time of making the contract as a reasonable consequence of a breach of it on his part. Judgment was accordingly given in the plaintiff's favour for the amount of the findings of the jury.

THE ASSOCIATION OF INFANT CONSULTATIONS AND SCHOOLS FOR MOTHERS.—The mothercraft competitions organised by this association with a view to testing the skill of the mothers attending these societies in London will take place on Saturday afternoon, April 12th (the last day of Health Week).

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of York.—The report for 1911 presented by Dr. Edmund M. Smith (school medical officer) and Mr. E. E. Scott Galbraith (assistant school medical officer) is a clearly written, well presented piece of work, useful for both local and general purposes. Particularly to be commended is the inclusion of a section dealing with the work of the whole county, and presenting for consideration useful suggestions that have been made in other localities and which are suitable for general application. The facilities for treatment consist of a staff of three half-time school nurses (half employed as health visitors), who "follow up" cases, and of a clinic for such ailments of school children as ringworm, blepharitis, debility, and otorrhœa. An arrangement has also been made for the treatment of certain cases of ringworm by X rays at the York County Hospital. The scope of treatment is, however, to be extended by the appointment of an expert assistant ophthalmic school medical officer, a dental assistant school medical officer, and by giving facilities for the obtaining of cheap spectacles. During the year nine schools were seriously affected by an epidemic of ophthalmia, and two schools were closed from June 27th and June 30th respectively until after the summer holiday. The medical officers hope to record in the next report the establishment of an open-air school and of special classes for stammerers and for children nearly blind.

East Sussex County Council.—Mr. Alexander G. R. Foulerton reports that good arrangements for "following up" cases of defective children are made in East Sussex by arrangements with the local and county nursing associations, but the precise effect of these measures in obtaining treatment is not stated. A special report by Dr. Arthur Beeley finds that the nutrition of boarded-out children compares favourably with those in the workhouse. Mr. George Finch considers the question of the mid-day meal of children, who attend schools in the country districts and take a dinner basket to school. The dinners provided are very frequently unsatisfactory. A proposal is made to allow older girls to prepare a simple meal, and a useful menu is submitted as suggested by an evidently vigorous and alert woman teacher.

County Borough of Stockport.—The work in this town in 1911 was carried on by Dr. M. Gertrude Edis and a school nurse under the superintendence of Mr. H. E. Corbin. A "clerical assistant" also assists the medical officer during the inspections with the hope of setting the nurse free to get more treatment carried out. All the children having ringworm were kept under observation at two centres and made 702 attendances there. Arrangements for treatment, however, are not very effective. Practically no treatment even exists for defects of vision, and no treatment of any kind has been undertaken by the authority.

County of Kincardineshire.—The report of Dr. W. A. Macnaughton extends over the school year ending July 31st, 1912, and deals with the examination of 2179 children, of whom only 878 are returned as defective, including clothing and cleanliness. The standards used in estimating defects are not always, however, available in the report. A move is now to be made in the direction of "treatment," as a small Treasury grant is available for the purpose. One delightful feature of the report is that which records the effectiveness of the apparently unofficial arrangements which exist for the provision of a hot meal at midday for children at rural schools. Reciprocal services between school teachers and farmers result in good meals at trifling cost, much of the food being presented. A notice sent to a child with seriously defective vision brought the following reply, not quite to the point:

> SIR,—Send no more notices, my child is clean and healthy, and I will see that she does not attend your medical examination again.

Western Australia.—Mr. James W. Hope, principal medical officer for Western Australia, who also performs the duties of chief school medical officer, has an interesting account to give in his 1911 report of the progress of medical inspection of school children in that colony. The scheme of inspection was introduced in the year under notice, and it is hoped that within two years every child in the State will have passed under review. The total number of school children in 1911 was 35,476, and 7784 were examined up to the end of the year. The officers appointed for this work were the local medical officers of health or, in districts where no such official existed, the Government district medical officer. The central Government pays for the inspection a fee of 1*s.* per child inspected, *plus* charges for *mileage and for "sustenance."* Parents do not appear to be invited to the inspection, but they are informed of any defects found, and the intention is that if the parents are unable to provide the necessary medical treatment this shall be given at one of the Government institutions. Already the revelation of the prevalence of dental caries has led to the institution of a voluntary dental clinic, and a Government dental hospital is called for by the dentists. The plan of inspection and treatment is of a thorough character, and is partly modelled on that issued by the Board of Education in England. School nurses were appointed to assist certain of the medical officers from the beginning of the work. in some respects from ing the methods and detailed comparison is not profitable as the possible variations of opinion are so wide. But fewer serious dental defects are recorded, and more defects of vision and enlarged tonsils. Only 4 cases of phthisis were recorded in the 7784 children, and there were only 2 other cases of tuberculous disease. The children examined were distributed through 76 schools, with numbers on the roll varying from 7 to 708, the latter being one of those at Kalgoorlie; but of eeth and cleanliness) In Australia, as in m to follow as the corollary to school medical inspection. We must heartily congratulate Mr. Hope on the thorough way in which the problem of inspection has been tackled, and trust that of the mistakes and experiences of this country and of We are especially open-air school. why every school should not be an open-air school, and taxpayers, teachers, and taught be freed from the expense and tyranny of too much and too solid bricks and mortar.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 7794 births and 5636 deaths were registered during the week ended Saturday, March 22nd. The annual rate of mortality in these towns, which had been 18·0, 17·4, and 17·0 per 1000 in the three preceding weeks, further declined to 16·5 per 1000 in the week under notice. During the first twelve weeks of the March quarter of this year the mean annual death-rate in these towns averaged 16·9, against 17·5 per 1000 in London during the same period. The death-rates during the week under review ranged from 7·1 in Hornsey, 7·7 in Smethwick, 8·1 in Bournemouth, and 9·6 in Ilford and in Willesden, to 23·8 in Sto 24·4

The number recorded in the previous week, and included 451 which were referred to the principal epidemic diseases, against 439 and 464 in the two preceding weeks. Of these 451 deaths, 220 resulted from measles, 72 from whooping-cough, 67 from infantile diarrhœal diseases, 51 from diphtheria, 28 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, against 1·3 and 1·4 in the two preceding weeks. The deaths attributed to measles, which had been 263, 206, and 229 in the three preceding weeks, slightly fell to 220, and caused the highest annual death-rates of 2·2 in Walsall, 2·3 in Plymouth, 2·4 in Barrow-in-Furness, 2·7 in Wolverhampton, 3·4 in Wigan, 3·7 in St. Helens, and 9·1 in West Bromwich. The deaths referred to whooping-cough, which had been 78, 68, and 83 in the three preceding weeks, declined to 72, and included 23 in London, 8 in Liverpool, 6 in Stoke-on-Trent, 4 in Nottingham, and 3 in Manchester. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had been 76, 81, and 69 in the three preceding weeks, were 67 in the week under notice; 25 deaths were recorded in London, 6 in Liverpool, 4 in Manchester, 3 in Stoke-on-Trent, 3 in Birmingham, and 3 in Salford The 51 deaths attributed to diphtheria were 1 below the average number in the five preceding weeks, and included 8 in London, 5 in Birmingham, 4 in Manchester, 3 in Liverpool, and 3 in Barrow-in-Furness. The deaths referred to scarlet fever, which had been 29, 18, and 23 in the three preceding weeks, rose to 28; 5 deaths were registered in Birmingham, 4 in London, 4 in Manchester, 2 in Preston, and 2 in Newport (Mon.). The fatal cases of enteric fever, which had been 8, 12, and 9 in the three preceding weeks, rose to 13, and included 2 in Rochdale and 2 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily declined from 2112 to 1556 in the twelve preceding weeks, had further fallen to 1514 on Saturday, March 22nd; 156 new cases were admitted during the week, against 183, 160, and 164 in the three preceding weeks. These hospitals also contained on the 22nd ult. 930 cases of measles, 905 of diphtheria, 284 of whooping-cough, and 43 of enteric fever, but not one of small-pox. The 1490 deaths from all causes in London were 36 fewer than the number in the previous week, and were equal to an annual death-rate of 17 2 per 1000. The deaths referred to diseases of the respiratory organs, which had been 453, 403, and 405 in the three preceding weeks, declined to 390, but were 144 above the number recorded in the corresponding week of last year. The deaths attributed to influenza, which had been 25, 40, and 53 in the three preceding weeks, further rose to 65 in the week under notice.

Of the 5636 deaths from all causes in the 96 towns, 159 resulted from different forms of violence and 366 were the subject of coroners' inquests. The causes of 47, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 53 other smaller towns. The 47 uncertified causes of death included 9 in Birmingham, 5 in Darlington, 4 in Liverpool, 4 in Gateshead, and 3 in Southend-on-Sea.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8620 births and 5792 deaths were registered during the week ended Saturday, March 29th. The annual rate of mortality in these towns, which had steadily declined from 18·0 to 16·5 per 1000 in the four preceding weeks, rose to 16·9 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 16·9 against 17·5 per 1000 in London during the same period. The death-rates in the several towns last week ranged from 7·6 in Eastbourne, 9·3 in Wallasey, 9·6 in Enfield and in Gillingham, and 9·9 in Willesden, to 22·6 in West Bromwich, 23·1 in Stoke-on-Trent, 23·9 in Wakefield, 24·5 in Wolverhampton, and 24 6 in Bootle.

The 5792 deaths from all causes in the 96 towns were 156 in excess of the number in the previous week, and included 410 which were referred to the principal epidemic diseases, against 464 and 451 in the two preceding weeks. Of these 410 deaths, 208 resulted from measles, 71 from infantile diarrhœal diseases, 67 from whooping-cough, 37 from diphtheria, 19 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·2 per 1000, against 1·4 and 1·3 in the two preceding weeks. The deaths attributed to measles, which had been 206, 229, and 220 in the three preceding weeks, declined to 208 last week, and caused the highest annual death-rates of 2·6 in Bolton, 2·7 in Wimbledon, 2·8 in Smethwick, 3·0 in Edmonton and in Stockton-on-Tees, 3·1 in St. Helens, 3·5 in Bury, and 4·1 in Gloucester. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 81, 69, and 67 in the three preceding weeks, slightly rose to 71 last week, and included 18 in London, 6 in Birmingham, 6 in Liverpool, 4 in West Ham, and 4 in Salford. The fatal cases of whooping-cough, which had been 68, 83, and 72 in the three preceding weeks, fell to 67 last week; 22 deaths were registered in London, 4 in Birmingham, 4 in Liverpool, and 3 each in Brighton, in Manchester, and in Newcastle-on-Tyne. The deaths attributed to diphtheria, which had been 54, 51, and 51 in the three preceding weeks, declined to 37 last week, which was the lowest number recorded in any week of the past quarter; 12 deaths were recorded in London, 3 in Birmingham, 2 in Manchester, and 2 in Leeds. The deaths referred to scarlet fever, which had been 18, 23, and 28 in the three preceding weeks, declined to 19 last week, of which number 3 occurred in Birmingham, and 2 in Leeds. The fatal cases of enteric fever, which had been 12, 9, and 13 in the three preceding weeks, fell to 8 last week, and included 2 which were recorded in Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined from 2112 to 1514 in the 13 preceding weeks, had further fallen to 1455 on Saturday last; 168 new cases were admitted during the week, against 160, 164, and 156 in the three preceding weeks. These hospitals also contained on Saturday last 908 cases of diphtheria, 880 of measles, 290 of whooping-cough, and 42 of enteric fever, but not one of small-pox. The 1510 deaths from all causes in London were 20 in excess of the number in the previous week, and were equal to an annual death-rate of 17·4 per 1000. The deaths referred to diseases of the respiratory organs, which had declined from 453 to 390 in the four preceding weeks, further fell to 380 last week, but were no fewer than 189 above the number registered in the corresponding week of last year. The deaths attributed to influenza numbered 46, against numbers steadily rising from 25 to 65 in the four preceding weeks.

Of the 5792 deaths from all causes in the 96 towns, 219 resulted from different forms of violence, and 470 were the subject of coroners' inquests. The causes of 51, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Portsmouth, Salford, and in 65 other smaller towns. Of the 51 uncertified causes of death, 13 were registered in Birmingham, 7 in Liverpool, 4 in Darlington, 3 in Bootle, and 2 each in London, Preston, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1032 births and 795 deaths were registered during the week ended Saturday, March 22nd. The annual rate of mortality in these towns, which had been 20·7, 19·9, and 18·8 per 1000 in the three preceding weeks, further declined to 18·4 per 1000 in the week under notice. During the first 12 weeks of the March quarter of this year the mean annual death-rate in these Scotch towns averaged 19·3, against 16·9 per 1000 in the 96 large English towns during the same period. Among the several Scotch towns the death-rate during the week under review ranged from 4·1 in Hamilton, 9·8 in Clydebank, and 12·0 in Kilmarnock to 20·1 in Greenock, 20·5 in Aberdeen, and 20·8 in Leith.

The 795 deaths from all causes were 21 fewer than the number in the previous week, and included 88 which were referred to the principal epidemic diseases, against numbers steadily increasing from 65 to 86 in the five preceding weeks. Of these 88 deaths, 55 resulted from whooping-cough, 18 from infantile diarrhœal diseases, 5 from measles, 5 from scarlet fever, 3 from diphtheria, and 2 from enteric fever, but not one from small-pox. These 88 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0, against 1·3 per 1000 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 55, 49, and 50 in the three preceding weeks, rose to 55, and included 33 in Glasgow, 7 in Edinburgh, 6 in Leith, 3 in Aberdeen, and 2 in Greenock. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 7, 15, and 17 in the three preceding weeks, were 18 in the week under notice; 8 deaths were registered in Glasgow, 4 in Aberdeen, 2 in Edinburgh, and 2 in Paisley. The fatal cases of measles numbered 5, against 7, 3, and 6 in the three preceding weeks, and comprised 4 in Glasgow and 1 in Falkirk. Five deaths, of which 3 occurred in Glasgow, were attributed to scarlet fever, against 4 in each of the three preceding weeks. The deaths referred to diphtheria, which had been 5, 12, and 9 in the three preceding weeks, declined to 3 and comprised 2 in Aberdeen and 1 in Glasgow. The 2 fatal cases of enteric fever were recorded in Kilmarnock and Falkirk respectively.

The deaths referred to diseases of the respiratory system in the 16 Scotch towns, which had been 180, 185, and 144 in the three preceding weeks, rose to 166 in the week under notice; 25 deaths were attributed to the several forms of violence, against 30 and 22 in the two preceding weeks.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1218 births and 744 deaths were registered during the week ended Saturday, March 29th. The annual rate of mortality in these towns, which had steadily fallen from 20·7 to 18·4 per 1000 in the four preceding weeks, further declined to 17·2 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Scotch towns averaged 19·1, against 16·9 per 1000 in the 96 large English towns during the same period. Among the several towns the death-rates last week ranged from 9·0 in Kilmarnock, 9·2 in Ayr, and 13·4 in Perth, to 20·1 in Greenock, 22·1 in Aberdeen, and 24·7 in Leith.

The 744 deaths from all causes were 51 fewer than the number in the previous week, and included 83 which were referred to the principal epidemic diseases, against numbers steadily increasing from 65 to 88 in the six preceding weeks. Of these 83 deaths, 44 resulted from whooping-cough, 17 from infantile diarrhœal diseases, 9 from measles, 7 from diphtheria, 3 from enteric fever, and 3 from scarlet fever, but not one from small-pox. These 83 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 1·2 per 1000 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 49, 50, and 55 in the three preceding weeks, declined to 44 last week, and included 29 in Glasgow, 4 in Leith, 3 in Edinburgh, 3 in Greenock, 2 in Aberdeen, and 2 in Motherwell. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had increased from 7 to 18 in the four preceding weeks, were 17 last week; of this number 9 occurred in Glasgow, 2 in Dundee, and 2 in Aberdeen. The fatal cases of measles, which had been 3, 6, and 5 in the three preceding weeks, rose to 9 last week, and included 4 in Glasgow and 2 in Aberdeen. The deaths attributed to diphtheria, which had fallen from 12 to 3 in the three preceding weeks, rose to 7 last week; 3 deaths were registered in Glasgow and 2 in Aberdeen. The 3 deaths referred to scarlet fever were slightly below the average in recent weeks, and comprised 2 in Glasgow and 1 in Aberdeen. The 3 fatal cases of enteric fever were recorded in Glasgow, Aberdeen, and Falkirk respectively.

The deaths referred to diseases of the respiratory system, which had been 185, 144, and 166 in the three preceding weeks, declined to 154 last week; 17 deaths were attributed to different forms of violence, against 22 and 25 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of this year, 546 births and 499 deaths were registered during the week ended Saturday, March 22nd. The annual rate of mortality in these towns, which had been 23·1, 23·2, and 23·4 per 1000 in the three preceding weeks, declined to 21·7 per 1000 in the week under notice. During the first twelve weeks of the March quarter of this year the mean annual death-rate in these Irish towns averaged 22·1 per 1000; in the 96 large English towns the corresponding death-rate did not exceed 16·9, while in the 16 Scotch towns it was equal to 19·3 per 1000. The annual death-rate in the week under review was equal to 21·6 in Dublin (against 17·2 in London and 19·5 in Glasgow), 25·0 in Belfast, 21·1 in Cork, 11·4 in Londonderry, 20·3 in Limerick, and 3·8 in Waterford, while in the remaining 21 smaller towns the mean death-rate was equal to 20·5 per 1000.

The 499 deaths from all causes in the 27 Irish towns were 40 below the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against 38 in each of the two preceding weeks. Of these 36 deaths, 14 resulted from measles, 7 from infantile diarrhœal diseases, 6 from enteric fever, 4 from whooping-cough, 2 from scarlet fever, 2 from diphtheria, and 1 from typhus, but not one from small-pox. The 36 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·6 per 1000; in the 96 large English towns the corresponding rate did not exceed 1·3, while in the 16 Scotch towns it was equal to 2·0 per 1000. The deaths attributed to measles, which had been 16, 18, and 13 in the three preceding weeks, were 14 in the week under notice, and comprised 6 in Newry, 5 in Belfast, 2 in Cork, and 1 in Wexford. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 9, 9, and 11 in the three preceding weeks, declined to 7, and included 4 in Dublin, 2 in Belfast, and 1 in Larne. The fatal cases of enteric fever, which had been 3 in each of the two preceding weeks, rose to 6; 3 deaths were registered in Dublin, 2 in Sligo, and 1 in Kilkenny. Of the 4 deaths attributed to whooping-cough, which were slightly below the average in recent weeks, 2 occurred in Dublin. The 2 fatal cases of scarlet fever were recorded in Belfast, those of diphtheria in Belfast and Sligo respectively, and that of typhus in Dublin.

The deaths referred to diseases of the respiratory system, which had been 143, 156, and 136 in the three preceding weeks, were 138 in the week under review. Of the 499 deaths from all causes, 143, or 29 per cent., occurred in public institutions, and 4 resulted from different forms of violence. The causes of 14, or 2·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 683 births and 547 deaths were registered during the week ended Saturday, March 29th. The annual rate of mortality in these towns, which had been 23·2, 23·4, and 21·7 per 1000 in the three preceding weeks, rose to 23·8 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual deate-rate in these Irish towns averaged 22·2 per 1000; in the 96 large English towns the corresponding death-rate did not exced 16·9, while in the 16 Scotch towns it was equal to 19·1 per 1000. The death-rate last week was equal to 24·2 in Dublin (against 17·4 in London and 17·6 in Glasgow), 24·5 in Belfast, 22·4 in Cork, 20·3 in Londonderry, 27·1 in Limerick, and 32·3 in Waterford, while in the remaining 21 smaller towns the mean rate did not exceed 21·2 per 1000.

The 547 deaths from all causes in the 27 Irish towns were 48 in excess of the number in the previous week, and included 46 which were referred to the principal epidemic diseases, against 38 and 36 in the two preceding weeks. Of these 46 deaths, 17 resulted from measles, 10 from whooping-cough, 8 from diphtheria, 8 from infantile diarrhœal diseases, 2 from enteric fever, and 1 from scarlet fever, but not one from small-pox. These 46 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0 per 1000; in the 96 large English towns the death-rate from these diseases did not exceed 1·2, while in the 16 Scotch towns it was 1·9 per 1000. The deaths attributed to measles, which had been 18, 13, and 14 in the three preceding weeks, slightly rose to 17 last week, and included 8 in Belfast, 5 in Newry, and 2 in Cork. The deaths referred to whooping-cough, which had averaged 5 in the three preceding weeks, rose to 10 last week, and comprised 7 in Dublin, 2 in Waterford, and 1 in Larne. Of the 8 fatal cases of diphtheria, which were double the average in the preceding weeks of the quarter, 6 were registered in Dublin, 1 in Belfast, and 1 in Larne. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 9, 11, and 7 in the three preceding weeks, were 8 last week, and included 4 in Dublin and 2 in Belfast. The 2 deaths referred to enteric fever were recorded in Cork and Lisburn respectively, and the fatal case of scarlet fever in Belfast.

The deaths referred to diseases of the respiratory system, which had been 156, 136, and 138 in the three preceding weeks, declined to 122 in the week under notice. Of the 547 deaths from all causes, 170, or 31 per cent., occurred in public institutions, and 14 resulted from different forms of violence. The causes of 19, or 3·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: J. Thornhill to the *Endymion*; and H. Woods to the *Vivid*, for R.N. Barracks.

ARMY MEDICAL SERVICE.

Colonel Edmund J. E. Risk is placed temporarily on the half-pay list on account of ill-health (dated March 27th, 1913).

Lieutenant-Colonel Henry M. Sloggett, from the Royal Army Medical Corps, to be Colonel (dated March 27th, 1913).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are restored to the establishment from the seconded list (dated April 1st, 1913):—Robert G. Shaw, Alexander L. Urquhart, and Avenell F. C. Martyn.

Colonel R. Kirkpatrick, C.M.G., has taken up duty as Assistant Director of Medical Services to the Abbottabad and Sialkot Brigades of the Second (Rawal Pindi) Division, Northern Army in India, in succession to Colonel R. I. D. Hackett, placed on retired pay

Lieutenant-Colonel H. P. G. Elkington, Senior Medical Officer and in charge of the Military Hospital at Shorncliffe, has been selected for the increased rate of pay under Article 317 of the Royal Warrant for Promotion. Lieutenant-Colonel A. W. Bewley, on return home from the Seventh (Meerut) Division, tour expired, has been appointed to the Northern Command for duty at York. Lieutenant-Colonel A. R. Aldridge, C.S.I., has been appointed in charge of the Medical Division of the Royal Herbert Hospital at Woolwich. Lieutenant-Colonel A. T. I. Lilly has been transferred from the Military Hospital at Colaba, Bombay, to Belgaum Cantonment. Lieutenant-Colonel S. Macdonald has taken up duty at Salisbury, on transfer from the London District. Lieutenant-Colonel L. Way has been transferred from the Military Hospital at Chakrata, Mussooree Hills, to Bareilly Cantonment. Lieutenant-Colonel R. J. Copeland has joined the Military Hospital at York. Lieutenant-Colonel F. R. Newland has been selected to hold charge of the Military Hospital at Dover.

Major C. E. P. Fowler has taken up the appointment of Instructor in Army Sanitation at the Royal Army Medical Corps School of Instruction, Aldershot, in succession to Lieutenant-Colonel A. R. Aldridge, C.S.I. Major H. W. K. Read has left Pontefract for a tour of service in India. Major S. J. C. P. Perry has been transferred from Belgaum Cantonment to the Military Hospital at Colaba, Bombay. Major A. D. Waring has been appointed to the Southern Command. Major J. W. S. Seccombe has taken up duty at the Military Hospital, Plymouth. Major A. H. O. Young has left Strensall for a tour of service in India. Major T. C. Mackenzie, D.S.O., has arrived home on leave of absence from Egypt. Major R. McK. Skinner has been appointed to the Irish Command.

Captain G. P. A Bracken has arrived home on eight months' leave of absence from Malapuram, Madras Presidency. Captain G. A. D. Harvey has joined the Royal Army Medical College. Captain E. W. M. Paine has been appointed for duty to the Western Command. Captain B. Varvill has been transferred from the Military Hospital at Quetta to Nasirabad Cantonment. Captain F. Forrest has been appointed to the Military Hospital at the Curragh Camp. Captain A. W. Gater has taken up duty at Winchester. Captain G. F. Rudkin has arrived home on six months' leave from Fort St. George, Madras. Captain R. D. O'Connor has been appointed to the Military Hospital at Lahore. Captain H. V. B. Byatt has been transferred from the Military Hospital at Poona Cantonment to Purandhur. Captain F. H. Bradley has taken up duty at the Military Hospital, Lucknow Cantonment. Captain E. M. O'Neill has been appointed to the Cork District. Captain C. R. M. Morris has been appointed to the Southern

Command. Captain W. H. Purdon has arrived home on leave of absence from Cannanore.

INDIAN MEDICAL SERVICE.

Director-General the Honourable Sir C. Pardey Lukis, K.C.S.I., has been granted combined leave of absence home from India for seven months, with effect from April 10th.

Lieutenant-Colonel B. H. Deare has been selected for appointment as Officiating Principal of the Government Medical College, Calcutta, during the absence on nine months' leave of Lieutenant-Colonel J. T. Calvert. Lieutenant-Colonel F. R. Ozzard has been granted one year's leave of absence home from India. Lieutenant-Colonel J. M. Crawford has been granted eight and a half months' leave.

Major E. C. MacLeod has been selected for appointment as a Civil Surgeon of the First Class under the Assam Administration. Major F. O. N. Mell has been granted 19 months' privilege leave home. Major J. C. Robertson has been nominated an additional Member of the Legislative Council of the Viceroy and Governor-General of the East Indies, in succession to Sir C. Steward-Wilson, K.C.I.E., resigned. Major A. T. Gage has been granted one year and eight months' combined leave of absence. Major E. F. Gordon-Tucker has relinquished charge of the Common Prison at Bombay. Major P. P. Kilkelly has been allowed an extension of furlough on medical certificate for six months. Major C. W. F. Melville has been selected for appointment as Deputy Assistant Director of Medical Services (Mobilisation Branch) to the First (Peshawar) Division *sub pro tem.*

Captain C. F. Marr has been selected for appointment as Officiating Medical Storekeeper to the Government of India at Lahore Cantonment, in succession to Major A. A. Gibbs, granted leave of absence. Captain G. T. Davy has been selected for appointment as Specialist in the Prevention of Disease. Captain F. S. Smith has been placed on special duty in connexion with serological work under Lieutenant-Colonel W. W. Sutherland. Captain M. L. Puri has been selected for appointment as Substantive Medical Officer to the 112th Infantry. Captain V. B. Nesfield has been appointed to officiate as Chemical Examiner, Government Analyst, and Bacteriologist for the United Provinces of Agra and Oudh and the Central Provinces, *vice* Dr. E. H. Hankin. The services of Captain H. C. Brown have been placed temporarily at the disposal of the United Provinces of Agra and Oudh. Captain A. W. Howlett, officiating civil surgeon at Mussooree, has been selected for appointment as Officiating Superintendent of the Central Prison at Bareilly. Captain C. C. Shaw has taken up duty as Medical Officer to the Raipur Central Jail. The services of Captain C. H. Barber have been replaced at the disposal of the Commander-in-Chief in India.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd South Midland Field Ambulance, Royal Army Corps: The undermentioned officers resign their commissions (dated March 29th, 1913): Major Seymour G. Barling and Lieutenant Samuel G. Webb. Captain George W. Craig to be Major (dated March 29th, 1913).

Attached to Units other than Medical Units.—Captain Alfred Alwyne Hingston, from the 2nd South Midland Field Ambulance, Royal Army Medical Corps, to be Captain (dated Feb. 18th, 1813).

For attachment to Units other than Medical Units.—John Thompson Shaw to be Lieutenant (dated March 29th, 1913).

DEATHS IN THE SERVICES.

Brigade-Surgeon Charles Frederick Oldham, late I.M.S., in his eighty-second year, at his residence, Great Bealings, Suffolk, on March 23rd. He served with the Perak expedition in 1875-76, and for his services received the medal with clasp. Later he took part in the Afghan war of 1878-79; also served with the Thal Chotiali field force and again received a medal.

Surgeon-Lieutenant-Colonel Alexander Brebner, A.M.D. (retired), on March 30th, in his seventy-third year. He received his first commission in 1863 and retired in 1888. He served with the Bhootan expedition of 1865, and was present at the recapture of Dewangiri (medal with clasp).

THE RED CRESCENT SOCIETY.

The Red Crescent Society has been in existence during a comparatively short period of time, but it has already done much excellent work. Eighteen months ago it had established numerous hospitals in Cyrenaica and Tripoli, and had expended at that time about £30,000. During the present war with the Balkan Allies it has doubled its activity, and its urgent appeals in all the parts of the Moslem world have received ready and liberal response, not only from the Ottomans in Turkey but also from the Islam worshippers of India, China, Egypt, Bosnia, and other places. The Convention of Geneva and the Conference of The Hague raised the society to an "Institution de Bienfaisance Internationale," whose regulations enjoin the rendering of assistance on the field of battle to wounded enemies of the non-Moslem as well as to those of the Moslem religion. The society is administered by a council of 30 members, who unite once a year in a congress. It has a president, two vice-presidents, a general secretary, an accountant and treasurer, all of whose offices are honorary, though the enormous pressure of work has necessitated the engagement of a number of employees who draw a monthly salary. The whole organisation is under the immediate control of the Ottoman Government. About two years ago Hussein Hilmi Pasha decided to create a number of hospitals with a chief medical resident, a surgeon, a physician with two attendants, a dispenser, a certain number of assistants recruited from the students of the medical faculty, ten experienced nurses, a secretary, a cook, and three servants to each. Every patient had to be supplied with a complete outfit of linen, and all requisites were, as much as possible, according to the demands of modern medical science. The following hospitals were established: 200 beds at Cadigra, Stambul, 600 beds at the University of Haidar Pasha, and 150 beds at the school of Vefa. In these hospitals alone thousands of sick and wounded, civil and military, have received most efficient treatment. Apart from the very laudable activity developed by the society in Constantinople, it took into consideration the needs of the provinces and especially of the two main armies of the East and West that were in operation on the Balkans, and for this work the society ordered from England four transportable hospitals with 100 beds each, and from Germany five complete collections of surgical instruments. After the renewal of hostilities the Red Crescent made every effort to meet all requirements. It established at the Dardanelles a lazaretto with 250 beds, and at Gallipoli one with 150. These lazarettos are almost exclusively for the severely wounded whose transport to the capital is impossible. A special hospital for both sexes with 150 beds has been established in Pera exclusively for the wounded arriving from the different places of the coast line of the Marmora Sea. A large hospital with 1000 beds, in which the Sultan takes a personal interest, has been established at the Military School of Pancaldi.

"Audi alteram partem."

HEREDITY AND TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—It may perhaps seem unbecoming to criticise the work of one who cannot answer objections, the more so when that one has but recently passed away, but there are certain conclusions in the clinical lecture of the late Dr. Theodore Williams, published in THE LANCET of March 29th, which are open to grave doubt, and the matter is one of such general importance that there need be no question of propriety in referring to these conclusions.

Briefly my objection is that, in spite of an initial warning, the more important part of the lecture shows a tendency to return to the pernicious teaching of hereditary transmission of predisposition to tuberculosis. I say pernicious not only because the doctrine is so grave in import to the general public that we have no right to fall back on it except as the last theoretical resort, but also because its tendency is to minimise, though ever so slightly, the environmental factor which we may expect to understand even more thoroughly, and over which we may expect to obtain a constantly greater control. There is at the outset of the lecture a confusion between what is meant by hereditary predisposition and congenital or antenatal infection. Scudamore's case, quoted by Dr. Williams, is an obvious example of the latter, a recognised though rare condition, and has nothing whatever to do with heredity. We see cases of congenital syphilis more often, but no one argues for a hereditary predisposition to syphilis.

While Dr. Williams's figures and generalisations as to the family relationship of consumptives may be accepted without question, they do not seem to support his conclusions (1) that both male and female phthisics transmit a tendency to the disease, and (2) that the male transmits a greater power of resistance than the female. Indeed, the transmission of a resistance against the disease, together with a tendency to it, seems somewhat of a paradox. The broad generalisation of the greater as well as the earlier influence of maternal tuberculosis has been reached by many authorities, but they have by no means drawn the same conclusions as Dr. Williams. For instance, Dörner, in an investigation on behalf of the Baden Ministry of the Interior (quoted in Köhler's "Results of Tuberculosis Research," 1911, p. 43), remarking on the same fact, concludes that it points to infective and not hereditary influence. He further finds that of children dying from tuberculosis in the first and second years of life 33·5 per cent. had a tuberculous mother, 14·7 per cent. a tuberculous father. There is no reason whatever in falling back upon vague hereditary transmissions of tendencies or specific weaknesses for an explanation of such facts.

Latham quotes Bang of Copenhagen as demonstrating that if the calves of tuberculous cows were removed at birth from their mothers it was possible to form a herd absolutely free from tuberculosis. Similarly, orphans through tuberculosis, when removed before too cumulative infection has occurred, prove as healthy as other children. We shall, I maintain, be absolutely at fault while we attribute to hereditary influences results which are clearly explicable by the cumulative effect of a tuberculous environment. The moral of which is that if we want to stamp out consumption we must begin at the beginning and remove children from infectious surroundings to some such institutions as orphanages.

I am, Sir, yours faithfully,
ARTHUR H. PRIESTLEY.
Norwich, March 31st, 1913.

THE POSITION OF THE DISPENSER UNDER THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The great transfer of dispensing to the chemist can only result in the throwing out of employment many persons who have spent their whole time as dispensers to doctors and institutions, many of whom have spent time in study, fees at colleges of pharmacy, and have secured the dispenser's diploma of the Apothecaries' Society. The most serious reflex has not yet been felt, their appointments tending to wane rather than to terminate abruptly. They represent a class of person who are in every way better fitted to do the dispensing for the insured persons rather than the assistant and junior of the trade who have done little dispensing in the past.

It is quite deplorable that the chemist is not requiring the institution or doctors dispenser to dispense under the Act. Analysis of advertisements (in a trade journal) made by myself shows more than three times as many situations open this year than last in the chemist trade. Only 4 per cent. of the advertisements referred to dispensers and 1 per cent. for the holders of the Apothecaries' Hall diploma. My position [illegible] affected has actuated [illegible] y with the help of my [illegible] put forward to plead our c[illegible] help would be re[illegible] profession. [illegible] nt from mem[illegible] an asset and [illegible] only be used generally in the very legitimate effort to get the right to be employed to do work which has been taken from us so ruthlessly by the trade which does not wish to employ us for economic reasons since 32 per cent. of the situations are for juniors and 27 per cent. for unqualified assistants of the trade.' "The qualified chemists wanted are chiefly for supervision purposes."

Allow me to thank the profession in anticipation of their favours, I am, Sir, yours faithfully,
GEORGE REED,
Dispenser.
The Provident Dispensary, 53, Surrey-street, Croydon,
March 31st, 1913.

WHEN TO OPERATE IN APPENDICITIS.

To the Editor of THE LANCET.

SIR,—Sir George Beatson has very kindly sent me a copy of his paper on Appendicitis, so that I might obtain the information I desired in respect to the results of his 300 cases. On examining these figures I find 126 were quiescent cases on admission, and therefore do not count in the consideration of the mortality occurring in acute cases. Of the remaining 174, 10 had general peritonitis, of which 7 died; 164 were acute, of which 69 only had abscesses, and 4 died. The total mortality in acute cases, therefore, works out at 6 2 per cent., a low figure, it is true, but not so low a one as many surgeons who operate early can show, and not so low as obtained recently at St. Mary's Hospital.

In reading these figures one is struck by the rarity of cases of general peritonitis, 10 out of 174, a proportion which does not correspond with the frequent incidence in London, 19 out of 136 (St. Mary's) (15 cases in my last 57). Again, a mortality of 70 per cent is exceptionally high. I think we should all feel very happy if our experience showed that 95 cases out of 174 would quiet down without suppuration. Certainly in my experience the proportion of suppuration in acute cases (admitted to hospital) is very much higher. Nor does Sir George Beatson mention the occurrence of multiple abscesses. He has no trouble with leaking or ruptured abscesses, and one is therefore compelled to infer that the resistant power of the Scotch peritoneum is much greater than that of the English.

Sir George Beatson acknowledges the benefit of early operation, but decides that it is not practicable. With this opinion I entirely disagree. At the present time, with competent modern surgeons in every district, telephones to summon them, and motors to bring them to a case, no patient *need* be left for more than 24 hours without being operated upon, except under very unusual conditions.

I am, Sir, yours faithfully,
W. H. CLAYTON-GREENE.
Devonshire-place, W., March 30th, 1913.

JOSEPH CLOVER.

To the Editor of THE LANCET.

SIR,—In your leading article on Joseph Clover in the last issue of THE LANCET you ask if he and Lister were at the first operation under an anæsthetic in Europe. I happen to know that Lister was, and in all probability Clover was also. He was in residence at the hospital in 1846, and so would naturally see anything remarkable that was going on It may be of interest to recall that he was what is now termed the R.M.O., in those days the "resident apothecary," and my father was one of the last to be "apprenticed" to him—i.e., what now corresponds to taking out a complete or perpetual hospital attendance ticket. This was in 1847. I quite agree with your appreciation of Clover's genius. As a young man I knew him well, and almost the last anæsthetic administered by him was to a member of my family. A quiet, kindly man with a genius for useful mechanical invention and a power of thought that was remarkable Some years after his death a late colleague of mine thought he would try and improve on Clover's small ether inhaler. He was able to study all Clover's models, and being an excellent mechanic himself, came to the conclusion that he could not improve on the original pattern. I only know one real improvement, that of the [illegible] friend Sir Frederic Hewitt. [illegible] was—calm, cool and encour[illegible] help to the surgeon. In his time there were few who followed the profession of chloroformist, and the giving of anæsthetics was often a rather haphazard performance by untrained practitioners. As an expert it was no wonder that Clover had the large practice which he deservedly enjoyed for a good many years.

I am, Sir, yours faithfully,

London, W., March 28th, 1913. F. WILLIAM COCK.

THE GENITAL FUNCTIONS OF THE DUCTLESS GLANDS IN THE FEMALE.

To the Editor of THE LANCET.

SIR,—Owing to an unfortunate concatenation of circumstances my first Arris and Gale lecture, which appeared in your issue of March 22nd, was published without being properly revised. For one thing, the lecture was published a week sooner than I expected, and as a result the corrected proof can only have reached you while THE LANCET was passing through the press—probably earlier than usual owing to the advent of Easter.

Apart from verbal and other small corrections, I regret to say that there are errors in some of the figures in Table I. These, of course, make the averages at the foot of Table I. (which should really be Table II.) inaccurate, although they do not affect the general results in any way. Further, it is obvious that the section dealing with the "Clinical Observations of the Effects Produced on the Thyroid by Ovarian Insufficiency in Women" should follow that on "Effects of Oöphorectomy on the Thyroid." As I believe no one can be too careful in the matter of accuracy either of style or scientific detail, I have felt it necessary to call attention myself to what has happened rather than leave it to someone else to do so. If anyone should be sufficiently interested in the subject and desire to have the correct figures I shall be glad to furnish him with one of the revised reprints which I hope will be available shortly.

I am, Sir, yours faithfully,

Liverpool, March 22nd, 1913. W. BLAIR BELL.

A REVISED NOMENCLATURE IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—Amongst the remarks you make about my article on sanatorium benefit in East Essex you say "the term 'early case' has gradually become almost synonymous with a 'favourable case,' and this is to be regretted since an 'early case' may be an acute case and quite unsuited for treatment in a sanatorium, a hospital being the more suitable institution." With this everyone must agree. Do you not consider that the time has come when the whole nomenclature in phthisis pulmonalis ought to be put on a definite footing, and that a fixed classification ought to be used throughout the country?

Now that the State has undertaken the crusade against consumption all the statistics will be of enormous value, and unless these are comparable in every respect this will be of little real value. If a committee was formed of such men, say, as Sir R. Douglas Powell, Sir T. Clifford Allbutt, Sir William Osler, and Dr. Arthur Newsholme, of the Local Government Board, a scheme acceptable to the whole profession could be formulated. The nomenclature could be adopted in the medical schools, &c., and would prove, I think, of the greatest use to those interested in sanatorium benefit. I am, Sir, yours faithfully,

J. D. MACFIE,
Tuberculosis Officer to the Essex County Council.
Chelmsford, March 31st, 1913.

AUTO-VACCINATION IN TUBERCULOSIS BY THE X RAYS.

To the Editor of THE LANCET.

SIR,—While agreeing that for a man to have a grievance is abominable, it is with no view to self-advertisement that I desire to draw your attention to the plagiarisms of the original article on the above subject contributed by me to THE LANCET in January, 1907, garbled versions of which appear from time to time as abstracts from foreign journals in the medical press of this country, where the credit for this particular research is ascribed to foreign authors, who do not hesitate to use expressions that I have found it necessary to coin, without so much as citing the source of their information.[1]

I trust, therefore, that you will pardon my writing at length on this matter. Conspicuous amongst these is a Swiss practitioner in the *Correspondenz-Blatt* of Basel, who contributes an original article to that journal "On the Conservative Treatment of Tuberculous Glands."[2] In that article he uses the expression "auto-vaccination," which has been interpolated by the translator into "some kind of auto-inoculation."

My object in using that expression was to connote a physiological as distinguished from a pathological process, such as auto-inoculation so often is, and consequently fraught with danger. While the author cites one British author (Gulland) in the usual manner, he curiously cites Dr. Peter Paterson (whom I cited in my article) without giving the clue to Paterson's article by any footnote, spelling his name in the German or Norwegian fashion (Patersen) he omits reference to my article, the one with which he seems to have been mainly concerned.

It is not for me to exaggerate the importance of my research, which has not yet been repeated in this country, but I can assert from my experience that the operation for the removal of tonsils alone would thereby be reduced 80 per cent., with the greatest advantage to the sufferers, from the point of view of restoring immunity, when applied before the suppurative stage has set in. One dare not publish them on account of the *odium theologicum* that unfortunately exists. But a careful study of the results that have been obtained in Berlin, Paris, and Basel, to mention a few, goes strongly to support my contention. Quite apart from the mere results, these researches throw light upon the lymphoid and lymphatic mechanisms of the body in their bearing upon pathological processes of an undreamt of kind, such as will before long establish "the logan stone" of our science upon surer foundations.

I am, Sir, yours faithfully,

Harley-street, W., March 31st, 1913. H. D. MCCULLOCH.

A QUESTION IN LUNACY CERTIFICATION.

To the Editor of THE LANCET.

SIR,—Dr. Robert Jones, in remarking on the slackness of justices in the matter of lunacy certification in your last issue, might very well extend his valuable advice to the medical profession in general. It is astounding how ignorant are medical men on the mere bare facts of the Lunacy Acts. It is excusable, too, since it is only in private and public mental hospitals where the practice of the laws of lunacy can be thoroughly studied. And the pitfalls are many, even to those who are in the actual practice of lunacy, so it is not surprising to learn of the errors of the unprofessional and unpaid layman, the justice. In my opinion every medical man in general practice should hold a certificate in psychology or give proof of a sound training in this branch of his profession. The provision in the Lunacy Act, 1891, on the matter of the text of this letter, was undoubtedly a convenience to meet such cases where other justices than the judicial authority had signed the reception order. And the wording of the Lunacy Act, 1891, Section 24 (3), is simple enough, for it says:—

> *A reception order made after the passing of this Act shall not be invalid on the ground only that the J.P. who signed the order shall appear to have not been duly appointed under Section 10 of the principal Act, if the order is within 14 days after its date approved and signed by a judicial authority.*

But surely it is the duty of the certifying physician to see that this is in order, for is there not a circular letter by the Commissioners in Lunacy, embodied in Archbold's "Lunacy," pointing out that all persons concerned with lunatics should make themselves acquainted fully and textually with the provisions of the Lunacy Acts? And as medical men are paid for signing lunacy certificates, and justices receive no remuneration, excepting the stipendiary, should not the former know their business, whatever may be the failings of the latter? I am, Sir, yours faithfully,

JOHN FREDK. BRISCOE.

Westbrooke House, Alton, March 31st, 1913.

BREAD AND THE SPREAD OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In reply to Dr. A. H. Priestley's letter in THE LANCET of March 22nd, in which he says it would be interesting to know if any investigations into bread as a source of conveyance of tubercle bacilli have been carried out, and, if so, with what result, I would refer him to some experiments by M. Auché as to the destruction of tubercle bacilli in bread. The French experimenter mixed some tuberculous sputum with dough, which was then baked. Apparently the heat of the baking destroyed the bacilli, for guinea-pigs which were inoculated with a bouillon made with some of the bread-crumb were not infected with tubercle. M. Auché, however, did not consider that the experiment proved that bread made from tuberculous dough was necessarily safe, for in the case of large loaves the central parts may not always attain the temperature necessary for the destruction of the bacilli.

I am, Sir, yours faithfully,

London, March 26th, 1913. W.

⁂ The experiments were reported by our Paris correspondent.—ED. L.

THE NUMBER OF MEDICAL MEN IN EUROPE.

To the Editor of THE LANCET.

SIR,—With reference to the paragraph with this heading in the Budapest letter quoted from the *Orvosi Hetilap*, I think there must be some error in that paragraph stating that the number of medical men in the whole of Europe amounts to about 100,000. The following are some of the latest figures that I can obtain: Great Britain and Ireland, 32,600 (authority, the Medical Directory, 1913); France, 23,657 (20,809 medical men and 2848 dentists) (authority, your own Paris letter in THE LANCET of March 29th, 1913, taken from the official figures of the Direction of Assistance and Hygiene to the Ministry of the Interior); Germany, 32,449 (authority, Professor Schwalbe's German Medical Directory, as quoted in the Berlin letter in THE LANCET of Jan. 21st, 1911); Austria, 13,202 (authority, the Vienna letter in THE LANCET of March 18th, 1911, quoting official figures). These four countries alone total to 101,908. In addition, your correspondent gives 18,270 for Italy. He does not mention Russia, Holland, Spain, Portugal, Sweden and Norway, Denmark, and other countries. The *Kuracisto* has recently stated that there are 160,000 medical men in Europe.

I am, Sir, yours faithfully,

April 1st, 1913. STATISTICUS.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

The Tax on Old Cars.

AT a recent meeting of representatives of the Royal Automobile Club, the Automobile Association, the Institution of Automobile Engineers, the Society of Motor Manufacturers, and the Commercial Users' Association it was decided to ask the Chancellor of the Exchequer to receive a deputation on this subject. Old cars have now to pay on the horse-power as estimated by the bore of their engines, though their actual horse-power is by no means equivalent to modern engines of like size. The deputation will also urge the desirability of quarterly licences. This latter item is of importance, as at present anyone buying a car in September has to pay a whole year's licence merely for four months. It is suggested that there should be a 50 per cent. reduction in the amount of the annual licence fee for cars built during or prior to 1908, as since then engine efficiency has greatly increased.

A Concession to the Medical Profession.

The authorities at Metz, in Germany, have recently given permission to medical men to carry a small Red Cross flag on their automobiles, and have ordered that cars so distinguished shall be given precedence in traffic.

An X Ray Motor Car.

In the *Journal of the Roentgen Society* for January Dr. E. B. Hazleton describes how a complete X ray apparatus may be carried in a compartment at the back of an ordinary motor car. The one mentioned does not weigh more than a passenger, and is sufficiently powerful to demonstrate the presence or otherwise of a stone in the kidney. The dynamo is run off the clutch shaft through a special countershaft connected to it by means of a chain, the gears, of course, being in neutral. Dr. Hazleton suggests that the wires from the secondary coil may be brought into the house through a window, or (which he considers better) the X ray coil and mercury interrupter may be taken into the room and the coil be connected by ordinary flexible light cables to the terminals of the dynamo. The current, of course, can also be used for lighting a room for operations or for electric treatment, such as light baths, electro-cautery, or vibratory massage. The fitting he describes can easily be adapted to any car, and the illustrations in his paper show well the method of construction.

Enclosed Front Seats.

Recently at the Guildhall court a private motorist was fined for driving a car with the driver's seat to a certain extent enclosed. The car was a two-seated one, fitted with a hood, wind screen, and side curtains, such as many medical men drive. The magistrate remarked that he considered the case a bad one and that the owner should have the hood cut right back. The law requires that the driver should have an uninterrupted view of the traffic on either side of him, and for the driver's own sake this is certainly desirable. In the case in question the side curtains were not fitted with windows. The fitting of celluloid windows in the side curtains would have complied with the regulations. It would thus be well for all ordering cars with cape hoods to see that the side curtains are fitted with windows.

A Useful Cleaning Brush.

Messrs. Brown Brothers, Limited, have recently introduced a new Duco cleaning brush which certainly seems well adapted for cleaning motor wheels. It has a curved end, which permits the user to remove the dirt between the spokes and the brake drum and from the inaccessible parts of the car under the frame which with the ordinary brushes cannot be got at, and are, therefore, usually left untouched.

The Duval Patent Spring Plates.

Springs are made of a certain number of laminations, the number depending on the weight of the car, and as a result of their position they are exposed to a great amount of wet, with the inevitable result that rusting may set in and ultimately prevent the natural sliding movements of the leaves, which, of course, defeats the very purpose for which the springs were originally designed. To obviate this, the springs should be taken off every six months or so, dismantled, and each member separately greased. As this is a troublesome operation it is generally not done. To solve this trouble, the Southern Automobiles, Limited, of Blackheath, have introduced the Duval plates. These plates are made of non-corrodible bronze, perforated to receive a specially prepared solidified lubricant, and they are inserted between the steel plates of the springs. The result is a non-rusting flexible spring, maintaining its resiliency and ensuring comfortable travelling. The cost of fitting is about 14*s.* per spring.

The New "G.R." Doctor's Coupé.

Original features are not lacking in this car, which I recently tried on the road. This small coupé, in my opinion, is essentially of the type that most medical men really need, whether for long-distance country work or for town visiting, and is equally comfortable whether used open or closed. I found after severe testing that it would go practically anywhere where there is a road, and was also quite comfortable, vibration, even on the roughest track, being reduced to a minimum. It proved to be economical in petrol, and should be the same with regard to tyres. Those desiring high fuel economy must be satisfied with small cylinders, and, providing the driver does not mind using at times his gearbox, small engines such as that in the doctor's "G.R." coupé are as efficient as and much cheaper than larger ones. If there can be any indication from the stroke and bore ratio, there should be peculiar advantages arising from the combination of 65 mm. bore and 110 mm. stroke. The engine, which has four cylinders cast *en bloc* of these dimensions, undoubtedly develops in ordinary use greater power than would be expected from an engine of this cubic capacity, and for a coupé the body in this car is exceptionally roomy, there being ample space for three in the interior.

In fact, the car was taken for a hundred miles' run with that number. The valves are all placed on one side of the engine, and are interchangeable. The distribution gear is driven by skew gearing, the magneto is set across the front, and the oil pump is driven at the bottom end of the magneto shaft. Some makers have spoken of inaccessibility as a virtue, suggesting that the inconvenience in itself prevents the mechanism of their cars being tampered with. The Unic Company, who make this car, I am glad to note, do not think in this way: everything is get-at-able. A single screw and the magneto is disconnected; by turning a thumb-screw the plate covering the adjustable valve lifters comes away, and by undoing a casing the carburetter jets can be taken out. But it is not likely that the jets will need attention, as the filter on top of the float chamber practically prevents any dirt from entering the carburetter, and in addition there is a gauze strainer in the float chamber. Lubrication is by pump through a hollow crank shaft to the bearings of that member and connecting rod, whilst an indicator on the dashboard shows that the oil is circulating. The clutch is of the leather-faced cone type, and fierceness is avoided by laminated springs fitted below the leather on the male portion. The withdrawal mechanism is well designed, and a clutch stop automatically slows down the top shaft in the gearbox, so that the speeds can be changed without sound or jar. Four forward speeds and a reverse are provided, controlled by a lever working in a gate, a stop on the reverse obviating getting into this gear by mistake. The brakes are of the internal expanding variety, the side ones operating on drums fixed to the back wheels, and the foot brake on the transmission at the back of the gearbox. Both are most efficient, and can be easily adjusted, but I must say I should prefer a pedal-applied brake acting directly on the rear wheels, and a side lever brake on the transmission. This method relieves the transmission mechanism and universal joints of work which, with the usual pedal brake, most drivers call upon them to bear. For cooling purposes thermo-syphonic circulation is relied upon, and on the test was found most satisfactory, the engine being quite cool after a severe hill climb. The steering is very easy, and the control pedals are conveniently placed. Personally I like the accelerator pedal to the right of the brake pedal instead of between it and the clutch pedal, but a driver would soon get used to the latter position.

As a result of an afternoon spent in driving the car I consider it sufficiently fast, lively, and very comfortable. As a thoroughly and conscientiously contrived piece of work it is well worth the consideration of a practitioner in search of a car of this character. The price with a coupé body complete is £330, and the agents are Messrs. Mann and Overton, Limited, of 10, Lower Grosvenor-place, London, S.W.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 922.)

V.—THE WORKING OF THE ACT AT CARLISLE.

The County of Cumberland and the City of Carlisle.

EXCEPTING the city of Carlisle, all the medical profession in Cumberland, as far as I can gather, condemned the Insurance Bill during its passage into law. From the first, indeed, doubts were entertained in Carlisle as to whether the cloud had not a silver lining. As far back as October last five practitioners in Carlisle expressed their willingness to go on the panel and their approval of the Act. These practitioners were very severely criticised by their colleagues. The practitioners of Cumberland held out well in defence of what they considered to be threats at their professional position; none went on the panel before Jan. 1st. But the leading of the British Medical Association then failed to retain the confidence of many, and the feeling of apprehension spread. The city of Carlisle has a population of 48,000, and forms a district under the Act. But a Greater Carlisle will be incorporated in the course of a few months, and the enlarged city will possess a population of about 60,000. In the meanwhile there is a local panel formed out of the 40 or so practitioners in the city, on which there are 13 practitioners. But it seems not unlikely that these practitioners would act on different tacks if some energetic steps had to be taken. Some are far more friendly to the Act than others, and some are not popular among their colleagues. As far as I could gather, out of 13 men on the panel nine are in favour of the Act. In the county of Cumberland 120 practitioners are on the different panels out of about 160 practitioners, a larger proportion much than we find in the city, yet the county is not so much in favour of the Act as the city is. Again, the two medical representatives upon the Carlisle Insurance Committee, elected by the whole profession of the city, naturally represent the views of the majority, and so the nine medical men in favour of the Act have no elected representative upon the Committee.

A Favourable View of the Act in Carlisle.

In my previous inquiries, hitherto in the South of England, I had for the most part heard the Act abused from various points of view. Now I was to have an opportunity of meeting some of its partisans. I interviewed one of the nine practitioners on the panel, who said at once that he was pleased with the working of the Act so far. He was receiving better pay and keeping more regular hours. He had no longer the trouble of dispensing, and he was overjoyed at being liberated from the thraldom of a lay committee composed, for the most part, of ignorant working men. Under the rules of his previous club practice the club members used to pay him 3*s*.—recently raised from 2*s*. 9*d*.—per year per member. Formerly in Carlisle, he said (and I know it to be the case), there were clubs that did not pay their medical officer more than 2*s*. a year per member for medical insurance. To-day under the Act the club doctor receives, instead of 3*s*. or 2*s*., 7*s*. How was it possible, he asked, to doubt that this was an improvement? Then, again, in the case of complaints, the Medical Service Subcommittee established by the Act should give a better trial and a more impartial verdict than the committee of some club or Friendly Society. "Further," urged my informant, "once on the panel always on the panel, while under the old club system the medical officers of clubs and medical aid societies could be dismissed at any moment at the caprice of a lay committee." Considering the difficulty of earning enough to live upon when contract work only brought in from 2*s*. to 3*s*. per head per annum, I inquired how many persons he thought a practitioner should have on his list. The answer was that the practitioner should not have more than from 1500 to 2000 on his list, and that this would leave room for private practice. This figure, I understand, is one that has been generally adopted as reasonable, though the margin of time for any private practice must be slender. My next inquiry was about the attitude of patients towards himself. He said that he found panel patients more civil than the old club patients had been. The latter would seem to be saying: "I pay my club fee and you are my servant." The Act, on the contrary, imposes regulations on the insured patients. They cannot order their medical attendant about; they will hesitate to threaten to complain against him and have him dismissed, as they know that such threats are idle. I pointed out that the Act was likely to cause many private patients to become insured persons, and that this might be a serious loss to many practitioners. My informant admitted that this was undoubtedly so. He himself, he said, had lost about 30 per cent. of his private patients who were now insured persons, while he admitted that some other practitioners in Carlisle had lost at least 50, and perhaps even 70, per cent. of their private patients. He summed up this situation, however, by saying that formerly not only private patients failed to pay, but even clubs and medical aid societies occasionally came to grief. Under the National Insurance Act he expected to make no bad debts.

Panel Practice and Scientific Progress.

Calling on another practitioner, who from the first had pleaded in favour of the Act, he told me rather ruefully that it kept him terribly busy. The Act was undoubtedly a great improvement on the old order of things. It was quite evident, he thought, that it would do a great deal of good, but his premises were now so crowded that he very much feared he would be compelled to get a new house. Beneath the complaint of this practitioner I thought that I detected a certain satisfaction with the condition of things. The next practitioner on whom I called had his house full of patients. They were being accommodated practically all over the house, and it was a matter of some difficulty to find a chair on which to wait for a favourable moment to speak to this overworked panel doctor When I met him he gave me his views at once He had more work to do now the Act was in force, and "such a number of trivial ailments" He had not more visits to pay, but so many insured persons came to see him at his surgery When he told them there was nothing the matter they replied that they were very glad to hear it They did not really think they were ill, but as they had been paying insurance money they thought they might as well come and make sure In that manner they would get some return for their outlay Then there was the signing of the certificates that entitled insured persons to claim sick allowance and the various benefits These certificate forms were not uniform, but differed with the different approved societies Each society would insist on complicating matters by having its own form There was not one certificate to say that a man was fit to return to work and another to say that he was not fit [illegible]

[illegible] developments and progress of science With a private practice no panel doctor should have more than 2000 names on his list, said this gentleman, and they must all be living within two miles or so The Act would do great good, he thought, to many poor people, but it would hinder the scientific progress of medicine The panel practice would fall, he feared to the level of the old club practice, the practitioner would get wearied out by trivial cases The best hope for medical science lay in the fact that some insured persons were not availing themselves of their red cards, but remained private and paying patients Here, then, was a partisan of the Act who was prospering as a panel doctor, but who nevertheless saw that there were dangers, and that medical men who devoted themselves solely to contract work were not likely to render much service to science, so deadening would be the routine, and perhaps so arduous the work

An Income Doubled under the Act

My next interview was with one of the most successful of the panel doctors, at least so I judged him to be He was hardly able to realise his own good fortune When once he understood the purport of my visit he conducted me to the window and begged me to look at a powerful motor car standing outside his door He had scarce worked under the Act for two months, and already he could buy a motor regardless of expense He had been making about £600 a year in private practice now he had some 2500 insured persons on his list, bringing him in about £900 It was true that his private practice had decreased by one-third, two thirds remained, and the third who had become insured patients was not all loss, as they had come to him as their panel doctor The Act, said this practitioner, was a splendid measure so long as the principle of the free choice of doctor was strictly maintained Formerly contract work was *parcelled out by the clubs The medical practitioners* had to pay court to committees of management, the patients had little or no voice in the matter Now any practitioner who really wanted to work had a fair chance He had only to make himself popular It was true they were having a lot of trouble in getting the service started Newly insured persons came with trivial ailments for the novelty of the thing, but that would all wear out, and if surgery attendance had much increased visiting patients at their own homes had not, and that was a most important side of the question A rumour had been circulated that if insured persons did not get their red tickets at once they would not be able to obtain medical attendance Consequently, some 300 persons came to him on one single evening, blocking up the street The popular doctor signed the red cards in batches of 50, telling the owners to come back on another occasion to give the details This continued for several nights, but a great many who obtained his signature on their cards never gave themselves the trouble to return, so that he really does not know even the names of all those who may call upon his services "But this does not matter," he added, "I do not need a formal introduction, for, thank goodness, I have no patients who stand upon unnecessary ceremony They are going to be much more reasonable to manage than private patients were Three or four people can be seen in the time one private patient would take up. Then they take your word and readily submit to be examined, there is no bother, no lengthy explanation is needed, we can treat the disease and not the people"

Malingering

There was a phase of the work, however, which this cheerful informant viewed with apprehension, and that was malingering There were so many men who, having passed mid life, did not want to work, so they "had pains in the back" These are the cases that make it possible that the panel doctor who most readily grants certificates of sickness will acquire an unfair advantage—that is to say, that a certain class of patient will desire not to be treated by a medical man who looks very closely after malingering The difficulty may have to be met by the appointment of medical referees An insured person would not be allowed to change his medical attendant if he had been sent to a referee for malingering and the charge had been made good In regard to the wage limit, he did not think he had more than two patients whose incomes exceeded £102 a year, and who had come since January to be treated as insured persons There were so few above this proposed wage limit that he did not think they were worth bothering about Finally, he freely recognised he had been much abused by his fellow practitioners—they had even called him a scoundrel, but for all that he was very grateful to Mr Lloyd George and the Insurance Act The Act had been denounced as Socialism, but it was not a question of Socialism or anti Socialism, for those were political matters What they had to think about was the sick, especially the sick poor Would the medical profession be able to give more attention to the latter than they had done previous to the passing of the Act? He maintained that the poor would get a great deal more attention than formerly, and to call this Socialism would not make it any the less beneficent

The Working Class and the Act

I went also among the poor themselves to see how they responded to such sentiments It must be confessed that I did not find the Act was popular among many of the working class of Carlisle They complained that the work of administration is much more complicated than it was with their old clubs and Friendly Societies Perhaps it was only just to pay the administrators better, but this did not make for economy There was a great amount of unnecessary red tapeism, and the insured and those who were managing affairs were smothered with literature What was wanted was simplicity and more effective management When the workmen organised and managed methods of insurance among themselves they did the work without so much bother and so many complications One thing, however, the Act has done for the working classes in the Carlisle district It has greatly strengthened the Gas Workers and General Labourers' Union The Northern District Branch of this far reaching union of workers had attempted to start a benefit fund of their own, but were *not very successful* To-day, the benefit fund of this trade union has obtained recognition under the Act as an Approved Society Having thus become a State institution, any number of workers who hesitated to join have now come in, and this the working classes consider a great advantage But so far as the medical aspect of the case is concerned they are less appreciative They all instinctively see the advantage of the free choice of doctors, but they do not fully appreciate the harm that club practice did Again, they are feeling somewhat resentful against the general hospital, where treatment and admission are not so readily granted Patients are now frequently referred back to the panel doctors The workmen, who claim that they have subscribed liberally to the upkeep of the hospital, now threaten to withdraw their support, a difficulty which has always been foreseen For this, it must be remembered, is not a new trouble, but the working of the Act has necessarily accentuated it, as the hospitals all over the country have been compelled alike to sift the cases in the out patient departments, and to withstand the pressure upon their beds The finances of the Carlisle General Hospital, like those of many analogous institutions, are not at all flourishing Some fear that it may be necessary to municipalise the hospital In that case the medical *staff* would have the right to insist on being paid, and the cost would be greatly augmented The ratepayers therefore view this prospect with considerable apprehension. All over the country the workmen's contributions have been magnified in importance, and the charitable spirit that should influence such subscriptions has been obscured. Carlisle is experiencing this difficulty.

Of course, as the figures given above show, the majority of the medical practitioners in Carlisle do not approve of the Insurance Act. But so far I have heard so much against the Act that I think it right to repeat what those who are in favour of the measure had to say. This accounts for my somewhat one-sided relation of what I heard and saw at Carlisle.

(*To be continued.*)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Institutions and Insured Resident Officers.

AN important letter has been received from the National Health Insurance Commissioners regarding a "problem" which was discussed by the Salford board of guardians lately in reference to the treatment of resident officers who became non-resident during sickness. The general purposes committee of the board, with one dissentient, resolved to recommend that resident officers who remained within the institution be paid their full salary and required to refund the amount equivalent to the full amount of sick pay received from their Approved Society. In the case of officers preferring to leave the institution for treatment during sickness, it was recommended that they be paid their full salary and required to refund a sum equivalent to one-third the amount of the sick pay received under the Insurance Act. In reply to a letter from the dissentient guardian, the Commissioners state that the payment of wages during sickness, except under the provisions of Section 47 of the Insurance Act, is a question of private contract between the employer and employee, and is not affected by the operation of the Act. The fact that an employer pays contributions under the Act does not relieve him of any liability in respect of such contract, and no refund could legally be demanded on account of any benefit which the insured person had received.

An Analysis of Children's Diseases at Three Stages.

Mr. E. D. Simon, in an interesting address delivered in Manchester on what he called "Religion and Civics," differentiated three stages at which we have information as to the health of the child. These three stages, he said, were (1) the report of the medical officer of health on infant mortality; (2) that of the medical officer of the education committee as a result of inspecting children at the age of five when entering school; and (3) the result of inspection when they left school. In 1911, out of every 1000 children born in Manchester 156 died within the first 12 months. In middle-class families, where children had proper treatment, deaths within the first year were comparatively rare. As to illegitimate children, the death-rate in one district was more than 500 per 1000 of the illegitimate children born. A high death-rate meant a high damage rate, for one in every four inspected at the age of five proved to be suffering from comparatively serious ailments of the skin, eyes, ears, or breathing passages. It was found that 17,000 out of the 100,000 school children had "thoroughly bad" teeth. Infant mortality was largely due to the fact that the slum mother did not know how to give her child even those advantages open to her. For the majority of children the private dentist did not exist. The report of the Dental Hospital showed that of the 17,000 school children with thoroughly bad teeth only 100 were treated at that hospital. If a child had ringworm the mother had to lose half a day in visiting and waiting at a hospital. Money was spent in finding out what was the matter, but no attempt was made to put things right. Hence the speaker urged the establishment of school clinics.

April 1st.

DONATIONS AND BEQUESTS.—Contingent on the death or remarriage of his wife, the late Mr. Richard Stanway has left £1000 to the Eden Cottage Hospital, Broad Oak, Essex.—*Sir John Ramsden* has contributed £1000 to the fund for the extension of the London School of Tropical Medicine.

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Health of Workers in Pitch.

THE manufacture of patent fuel from pitch and coal dust is an increasing industry in South Wales, and especially in the neighbourhood of Swansea. The men who are employed in certain processes have been found to suffer from warty growths which in some instances have taken on an epitheliomatous character, and in certain instances the eyes of the workers have been affected. Reports which had been received led the Home Office to consider the desirability of scheduling the industry as a dangerous trade, and in the summer of 1911 a long inquiry was held in Swansea and Cardiff with a view to ascertaining the extent of the mischief done. No definite decision was arrived at as the result of the inquiry, as it was considered desirable to ascertain what would be the effect of carrying on some of the processes under cover and of providing bathing facilities for the men on the works premises. Several owners of works undertook to make the necessary structural alterations and a few of the men volunteered to make use of the bathing facilities. At a further inquiry recently held at Swansea and Cardiff the results which had followed these experimental safeguards were disclosed. The carrying on of the work under cover seems to have been successful, for the manager of one works where a large shed had been erected stated that since its erection there had been no case of the disease among the men employed there. The encasing of machinery and the more regular sweeping of the workplaces with a view to lessening the amount of dust scattered about appears to have had a good effect, but the bathing at the works has met with a great deal of opposition from some of the men, although in this connexion there was a difference of opinion among the men employed in Swansea and in Cardiff. The men's representative in Swansea said that the provision of baths had been greatly appreciated, and he considered they had had a beneficial effect, for the men who regularly bathed had become free from warts and their skin generally had improved. The Cardiff workmen, on the other hand, were opposed to the bathing at the end of the day's work, for they contended that it produced an acute burning sensation, especially on sunny days or when there was a cold wind. Some of the men declared that they would give up the work if compelled to have baths at the works. This difference may possibly be due to a different form of pitch being used in the two districts. It transpired during the inquiry that Mr. H. Campbell Ross was conducting some investigations into the relative action of different forms of pitch, and had already found that pitch made from Scotch coal was less deleterious than that made from the South Wales coal, and that there was a difference between blast-furnace pitch and gasworks pitch. It is probable that the results of his further investigations will be awaited before any decision is come to by the Home Office as to regulating the industry.

Sanatoriums for Wales.

An important part of the scheme of the Welsh National Memorial Association is the erection of sanatoriums in different parts of Wales. The association has already taken over the only two at present in use—the West Wales Sanatorium at Alltymynydd, near Carmarthen, which was opened in the summer of 1909, and a small institution in the Isle of Anglesey which it is now proposed to enlarge. A new institution is to be erected at once at Bangor for North Carnarvonshire, and another for South Carnarvonshire and Merionethshire near Barmouth. For Cardiff there are now in course of erection buildings at Glan Ely, and it is anticipated that in a few weeks they will be sufficiently advanced to allow of the admission of about 50 patients.

Isolation Hospitals in Glamorgan.

A noticeable feature in the recently issued report by the medical officer of the Local Government Board on the incidence in England and Wales of notifiable infectious disease during 1912 is the large number of cases of scarlet fever which occurred in Glamorgan. In the whole of Wales the rate per 1000 inhabitants was 3·35. In Aberdare it was 12·5 per 1000, in the Rhondda Valleys 6 per 1000, and in Ogmore and Caerphilly 7 per 1000. In recent [illegible] the Gelligaer urban district near Merthyr, where there is a population of nearly 40,000, a new hospital costing £12,000 has just been opened, and as there were 110 cases of scarlet fever in the district last year it would seem to have been established none too soon. Aberdare is very ill-provided with means of isolating cases of infectious disease, a small wooden building being the only available institution, although last year no fewer than 635 cases of scarlet fever were notified to the medical officer of health. A few years ago plans were prepared for a much larger hospital [illegible] further steps were taken with [illegible] a suitable site. [illegible]tion have now, however, been successful, and a site has been obtained at a cost of £8750.

April 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

County of Aberdeen and Sanatorium Treatment.

AT a conference between the public health subcommittee of the Aberdeen county council and representatives of the public health authorities of the county from the several burghs and district committees, held recently in Aberdeen, it was decided that sanatorium treatment should be undertaken for all persons requiring such treatment, including insured persons and their dependents, also uninsured persons. It was also decided to appoint a tuberculosis officer for the whole county. Representatives were present from Peterhead, Fraserburgh, Rosehearty, Ellon, Old Meldrum, Kintore, Inverurie, Ballater, Turriff, and Huntly, and from the district committees of Deer, Ellon, Garioch, Turriff, Aberdeen, Alford, and Huntly. With regard to the sanatorium question, only the four representatives from Turriff voted for an amendment to the effect that the negotiations be delayed in the meantime.

Lanarkshire Scheme for a Sanatorium.

A joint scheme for providing a dispensary service and sanatorium for the prevention and treatment of tuberculosis under the National Insurance Act has been considered by representatives of the burghs of Airdrie, Coatbridge, Hamilton, Motherwell, Rutherglen, and Wishaw, and various recommendations have been made. These include that a tuberculosis officer be appointed, at a salary of £500, to advise and assist the local authorities in arranging the details of the joint scheme, and to act as superintendent of the sanatorium when erected. It is suggested that such an officer should attend at least once a week at the hospital or dispensary in each burgh and in emergency cases when required. That otherwise the medical officer of health should carry out the work in each burgh, and be responsible to the local authority for the local organisation and the treatment of patients in the hospital. A subcommittee to whom the matter was referred agreed that provision should be made for 100 beds, and considered that a site of from 15 to 20 acres would be necessary, with the right to lease ground adjoining for the purpose of providing work.

Aberdeen Maternity Hospital.

At the first annual meeting of the Aberdeen Maternity Hospital the report for the year was presented. It states that the directors and representatives of the Approved Societies have been conferring, and it was hoped that an early and satisfactory arrangement might be come to, so that those obtaining benefit under the National Insurance Act might have attention either from the outdoor or indoor staff of the Maternity Hospital in return for adequate remuneration under the provisions of the Act. The directors are of opinion that meantime a charge of 10*s.* should be made for each case treated in the hospital, and 7*s.* 6*d.* for each case treated in the district; special cases to be specially arranged for with the societies. This arrangement may involve the appointment of a certificated nurse to attend specially to the outdoor cases. No progress could be reported with regard to obtaining some substantial assistance from the University, whose students benefit so largely from the teaching and practical training furnished by the hospital. They were hopeful, however, that some help might be forthcoming. 221 cases were treated during the year, an increase of 16 on the previous year, and 232 cases in their own homes, an increase of 5. All the outdoor cases were attended by the nurses of the hospital in addition to their indoor work. Forty-three students had attended the practice of the hospital, indoor and outdoor. From May 31st to Dec. 31st the expenditure exceeded the income by £143 2*s.* 3*d.*, and the expenditure from Jan. 1st to May 31st prior to the disjunction from the Aberdeen Dispensary exceeded the total deficiency on the ordinary working by £263, the total deficiency of the year being £407.

New Prison Commissioner.

The King has been pleased on the recommendation of the Secretary for Scotland to approve the appointment of Mr. James Devon, surgeon to His Majesty's prison in Glasgow, to be a Prison Commissioner for Scotland in place of Mr. Trotter Robertson, deceased. Mr. Devon is a native of Glasgow, having been born in the Calton in 1866. His early days were occupied with various activities, among his occupations being service in a house-factor's office and in a Bridgeton factory. He devoted his leisure to studying medicine, and in 1893 he became a qualified medical man. He was a house surgeon in the Royal Infirmary, Glasgow, and later assistant in the pathological department there. His first outside appointment was as assistant medical officer in the city poorhouse, and in 1895 he was appointed medical officer in Duke-street prison. In 1901 he became one of the three medico-legal examiners to the Crown in the Glasgow district. His promotion to the high office of Prison Commissioner will be very popular and is felt to be highly deserved. Mr. Devon has earned wide distinction as an authority on criminology, and has lectured extensively on the subject to the Royal Philosophical Society of Glasgow and other bodies. His book, "The Criminal and the Community," published in 1910, is a valuable work on prison management and criminology.

Glasgow Hospital Sunday Fund.

At the nineteenth meeting of contributors to this fund it was reported that the income of the fund for the year amounted to £4623, a decrease of £136 as compared with the preceding year. The sum set aside for allocation was £4410, and, as in previous years, a division was made in proportion to the number of fully occupied beds in each infirmary. The Royal Infirmary, with 638·2 beds, got £1946 15*s.* 7*d.*; the Western Infirmary, with 553·5 beds, got £1688 8*s.* 2*d.*; and the Victoria Infirmary, with 254 beds, got £774 16*s.* 3*d.*

Aberdeen Dispensary.

The annual meeting of the subscribers to the Aberdeen Dispensary and Vaccine Institution was held recently. During the year 9310 cases, as compared with 13,129 the previous year, have been treated, the decrease being probably in some measure due to the charge of 2*d.* now being made for medicines, and also partly to the fact that in 1911 there was an epidemic of measles. The number of patients treated in their own homes during the year by the general staff of the dispensary was 2355, compared with 3053 the previous year. The number of visits paid was 5951, compared with 7914 in 1911. Seventy vaccinations and revaccinations were done, a decrease of 7. 327 dental operations were performed, compared with 427 in 1911. Special ear, nose, and throat cases numbered 900, being a decrease of 123. 31,002 prescriptions, as compared with 47,292, were dispensed. The charge of 2*d.* now exacted for each time medicine is dispensed brought in £184 11*s.* 4*d.*, going a considerable way to meet the cost of medicine, which was £286 8*s.* 9*d.*, £46 1*s.* 3*d.* less than in 1911, thus showing a considerable decrease all round. To the post of medical officer, rendered vacant by the retirement of Dr. W. F. Croll, Dr. Middleton Connon, late of Montrose, was appointed.

April 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Benefit.

THE committee appointed to inquire into the desirability of extending medical benefits under the National Insurance Act to Ireland met for further sittings in Dublin on March 26th, when Mr. D. A. McCurdy, of Londonderry, Mr. W. J. O'Sullivan, of Limerick, and Mr. S. B. Coates and Mr. T. A. Davidson, of Belfast, were examined. Afterwards a conference took place between the members of the committee, the Irish Insurance Commissioners, and the members of the Conjoint Committee of the Irish and British Medical Associations. Lord Ashby St. Ledgers, the chairman, said that the Chancellor of the Exchequer had told him distinctly that all he could give for medical benefit in Ireland was the same as in England, 7*s.*, to pay for certificates, and medical and tuberculosis benefit, but exclusive of medicines and appliances. The suggestion was then made that in Ireland the medical practitioners should for this payment attend not only the insured but also their dependents, a proposition which the representatives of the Conjoint Committee absolutely refused to entertain or even to put before the profession, as they knew it would be useless to do so. The committee then explained that for the present their idea was simply to recommend the extension of medical benefit to the six county boroughs—i.e., Dublin, Belfast, Cork, Limerick, Londonderry, and Waterford—but they would like to include the dependents. They pointed out that as no more money was available from either the Treasury or the employers, the only other source was the insured themselves, and they asked if the Conjoint Committee would join in a round-table conference in London with the Treasury Committee and representatives of the Friendly and Approved Societies to see if some scheme could be suggested. If the Approved and Friendly Societies got their members to add an additional 1*d.* per week, the total sum for each insured person would be 11*s.* 4*d.*, and if from this was deducted 10*d.* for medicine, &c. (in addition to what is already estimated for medicine—i.e., 2*s.*—in addition to the 7*s.*) a sum of half a guinea would be available for medical practitioners for attending each insured person and his dependents. The Conjoint Committee agreed (after private consultation) to take part in this London conference, but said they could make no promises for the profession until that body was first consulted; so the matter is to be brought before the Local Medical Committees of the six county boroughs this week. Whether the profession in these towns will agree on any fixed rate is doubtful. In Belfast the profession have already decided that they would accept the same rates as in England —that is, 7*s.* for each insured person—and that they would attend each of the dependents at the same figure.

The Certification Scheme.

The scheme of payment for the provision of medical certificates under the National Insurance Act has been the subject of discussion in medical circles all over the country during the past week. There is a general feeling that the rate of remuneration is inadequate for the duties required. The decision whether to go on the certification panels or to decline has been left by the Conjoint Committee to the Local Medical Committees, who are summoning meetings of the profession to decide the matter for each area. Most of the meetings held up to the present have decided against the scheme—for example, county Dublin, county Tyrone, Queen's County, North Tipperary, county Cork, county Westmeath. On the other hand, some of the city areas, notably Belfast, Londonderry, and Cork, have agreed to form panels. Limerick has refused. It is curious that the chief opposition to the scheme comes from the rural areas, where the rates of payment offered are the highest. This opposition is probably due to the fact that in the country districts the Poor-law medical officers fear a large increase of work if they undertake the responsibility of certification. In the cities both Poor-law medical men and Friendly Society practitioners feel that almost any system of payment would be better than the present confusion. There is no denying the fact, however, that the scheme has given rise to acute differences of opinion in the profession. Some of the more extreme of the country dispensary practitioners interpret the qualified approval given by the Conjoint Committee to the certification scheme as an abandonment of their interests, and at a meeting held in Dublin last week they repudiated the Conjoint Committee as the executive of the profession.

The Royal Victoria Hospital, Belfast.

At the 120th annual meeting of the supporters of this hospital, held on March 26th, it was reported that 3321 new cases had been treated in the wards (2183 surgical and 1138 medical) during the past year, while in the extern department 32,658 patients had attended. Financially, the total receipts for the year were £16,514, as against £16,738 in the previous year, while the expenditure was £16,587, as against £16,394. The workmen's subscriptions, which had increased during the first six months, showed a decline at the end of the year.

The late Mr. Wm. John Meharry.

I regret to announce the death in his seventieth year of this well-known Belfast medical practitioner, which took place at his residence on March 30th. A county Down man, Mr. Meharry was at first in business in Liverpool and London, but in 1877 he returned to Belfast, and under his late brother's direction and advice (Dr. Hugh Meharry) he entered Queen's College, Belfast, as a medical student, and in 1883 became a Licentiate of the Royal Colleges of Surgeons and Physicians of Edinburgh. For 28 years he was, to the entire satisfaction of the Belfast guardians, apothecary under the Poor-law board. Mr. Meharry had a large practice and was deservedly popular.

April 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Congress of Gynæcology, Obstetrics, and Pædiatry.

THIS Congress was held at Lille from March 25th to 28th. Professor Pozzi, who presided at the opening meeting, pointed out that gynæcology, obstetrics, and pædiatry pursued a common end, the conservation and amelioration of the race —conditions indispensable to national greatness. M. Delasalle, mayor of Lille, welcomed the delegates, and after Professor Oui, the secretary-general, had delivered a brilliant address, Professor Bar, on behalf of the Société d'Obstétrique et de Gynécologie Française, proposed the formation of an association of French-speaking obstetricians and gynæcologists, which was unanimously adopted. In the scientific proceedings papers were read by M. Puech and M. Vanverts on Tumour of the Ovary in Relation to Pregnancy, and were discussed by M. Barnsby, M. J. L. Faure, M. de Fourmestraux, M. Muret (of Lausanne), M. Jullien, M. Le Nouène, M. Jokelmann-Bach, M. Jayle, M. Walther, and M. Pinard. Malignant chorio-epithelioma was considered in papers by M. Proust, M. Bender, M. Polosson, and M. Violet—first the pathological anatomy and pathogenesis, then the relation of chorio-epithelioma to gestation and teratomata from a clinical standpoint, with a description of the diagnosis, evolution, prognosis, and treatment. In the ensuing discussion M. Wallich, M. Bégouin, M. Violet, M. Proust, M. Bender, M. Keiffer, and M. Pinard took part. The members of the Congress were then divided into two groups, one of which visited the Maternité and the Charité, the other the St. Sauveur Hospital. On Wednesday the president, Professor Pozzi, gave a very successful reception, and Thursday was devoted to a visit to the mines of Lens and Auiche.

Exchange of Professorships.

M. Hartmann, professor of operative surgery at the Faculty of Medicine of the University of Paris, was transferred on March 1st, at his own request, to the chair of Clinical Surgery at the same faculty.

The Treatment of Tuberculosis by Marine Micro-organisms.

At a recent meeting of the Académie des Sciences M. Raphael Dubois stated that some years ago he had kept alive for 10 months guinea-pigs previously inoculated with cultures of the tubercle bacillus by injecting into them during the period of glandular enlargement cultures of a micrococcus taken from the pearl capsules of certain shellfish found on the sea-shore at Hyères M Dubois announced that he intended to resume his experiments

The Hygiene of Barbers' Shops

M Marc Langlais has undertaken to make a study of the number of microbes to be found in shaving brushes, combs, hair brushes, and other implements of the barber Many barbers becoming interested in the question and wishful to learn a simple method of rendering their apparatus aseptic, applied for information to the Institut Pasteur The reply was reassuring It appears that the microbes found by M Langlais are for the most part innocuous Simple methods of disinfection consist in a slight flaming of metal combs and razors Shaving brushes should be soaked in an antiseptic solution A formol heating steriliser similar to those used by surgeons for their instruments is recommended

Congress of Medical Students

The delegates from all the incorporated associations of medical students and three representatives of general associations were present at the first congress organised by the Federation of Incorporated Associations of France Various resolutions were carried first, to oppose, by legal recourse if necessary, the exemption from the baccalaureate , secondly, to demand that in principle appointments as interne of the hospitals shall be reserved for French students in the provinces particularly, except where French candidates are insufficient in numbers , thirdly, one relating to the organisation of the clinical appointments (*stage médical*) in the hospital services [illegible] the number of patients, in the proportion of one *stagiaire* to each six or eight patients Finally, the fourth demand is that the fifth year shall be freed from all laboratory work and exclusively devoted to clinical work , that the work to be done in the first four years and the examinations corresponding thereto shall be conducted on really practical lines, and not be allowed to degenerate into theoretical examinations to the detriment of the clinical examinations , and that the dates of examinations shall not synchronise with those of the competition for the Assistance Publique The questions concerning foreign students in France and the consequences of the prolongation of military service for medical students also formed the subject of interesting discussions

The International Town Life Exhibition of 1914

It has been decided by the city of Lyons to organise a town life exhibition there from May 1st to Nov 1st 1914 In this international exhibition the vast subject of collective life in the modern town will be demonstrated The exhibition will deal with the requirements of hygiene of transport the culture of man, puericulture, school, instruction work disease, tuberculosis alcoholism, old age invalidity and industry The following is a list of the sections statistics and demography , street control and modes of transport , drinking water , surface waters and the purification of water , evacuation of the solid residues , dwellings , furnishings , lighting and electric lighting , ventilation, heating, and refrigerating , foods of animal origin , milk and its derivatives , foods of vegetable origin , hygienic drinks , adulteration and inspection of food stuffs , mineral waters , special chemical hygienic products , infant protection and puericulture , school ; military hygiene , bodily hygiene and cleanliness , primary and secondary instruction , superior instruction , technical and professional instruction , the hygiene and protection of work , social economics , police of towns and police laboratories , infectious diseases , disinfection , organisation of public health in various countries , the departmental health services , assistance and the hospitals , the struggle against tuberculosis , the struggle against alcohol , touring , physical culture and sports , the arts , photography , books, posters, and newspapers , horticulture , electricity (other than lighting) , the postal, telegraph, and telephone services All exhibits relating to social or economic science will be admitted free, commercial exhibits alone being subject to duties

BERLIN.

(FROM OUR OWN CORRESPONDENT)

Unusual Combination of Clerical and Medical Functions

THE ecclesiastical and medical authorities of the Province of Saxony have recently had to deal with an unusual problem in medical ethics A medical man in a small country town complained to the medical chamber of the province that the clergyman of a neighbouring locality, who had been a qualified medical man before he entered the ecclesiastical profession was now undertaking medical practice and recovering fees, which were spent by him for benevolent purposes Before this clergyman was appointed to his present parish there had been no medical man resident in it, and patients had consulted the complainant, who lived not far away The complainant had, however, lost nearly all this portion of his practice, and things became worse when the clergyman was appointed honorary medical officer of the locality together with the medical man of the town The medical chamber accordingly transmitted the complaint to the ecclesiastical authority of the province with a request that the clergyman should be prohibited from accepting the appointment and also from acting as a medical practitioner The consistory, however, took a view of the case different from that of the medical chamber, saying that as the clergyman in question had a regular German medical qualification he was of course entitled to engage in medical practice They could only prohibit him from doing so if he neglected his clerical duties, a fault which he had not committed The consistory further stated that the only patients whom he attended were residents in his parish and that at their special request he had been appointed honorary medical officer of the parish, in which there was no resident medical man He did not receive any fees for this appointment, so that the neighbouring medical man who continued to act as medical officer and to receive the same salary as formerly had no real ground of complaint Far from prohibiting the clergyman from engaging in medical practice, the consistory wished him to continue his work in the interest of the parish The medical chamber thereupon decided to enter the clergyman in the *Medical Register* in the same manner as all other medical men residing in the province, to recover the tax for the medical chamber from him, and to bring him under their jurisdiction in questions of medical ethics

The Retirement of Professor Heubner

Professor Heubner the well known specialist for diseases of children, has left his post as ordinary professor of pediatrics at the University of Berlin and director of the pediatric department of the Charité Hospital At the occasion of his final lecture all his former and present assistants assembled in the lecture room together with the students Professor Finkelstein presented a "festschrift ' edited by the different assistants, and announced that a fund had been collected under the name of the Professor Heubner Fund for the support of clinical and therapeutical researches in pediatrics A premium from the interest of the fund is to be distributed every three years to workers in the above branch of medicine

Statistics of Deaf mutism

According to the statistical journal edited by the Prussian Statistical Office the number of deaf mutes in Prussia registered at the last Census was 34,804, of whom 18,659 were men and 16 145 were women It is remarkable that the relative number of deaf mutes has continuously decreased since 1871 , in 1871 there were 9 9 deaf mutes registered for each 10 000 of the population, but only 8 7 in 1910 The Eastern Provinces of Prussia have relatively the greatest number of deaf mutes, the ratio per 10 000 being 17, 16, 15, and 11 cases in East Prussia, West Prussia Posen, and Pomerania respectively In the Western Provinces, Rhenish Prussia, Saxony, Westphalia Schleswig Holstein, and in the district of Berlin only 5 to 7 cases occurred for each 10,000 The Jews have the largest proportion of deaf mutes—namely, 14 4 per 10,000 , among the Protestants the corresponding number is 9 9, whilst among the Roman Catholics it is 10 3 In the year 1910, of the men 27 5 per cent were married as compared with 13 per cent in 1880 The increase of marriages is certainly caused by the fact that a better training of the men enables them to provide a home. This is also illustrated by the fact that 2195, being 117·6 of each 1000, were established in independent positions as compared with 60·8 per 1000 in 1880. The majority of deaf-mutes are engaged in tailoring and in agricultural work. There are 48 institutions in which 5050 deaf-mute children are being trained by 612 teachers.

The Berlin Medical Society.

At the last general meeting of the Berlin Medical Society the honorary secretary, Professor von Hansemann, gave a report of the business of the society. He stated that the number of members was 1714, of whom 22 were honorary and 9 were life members. The society had met 34 times, when 44 lectures were delivered. The number of members had increased by 93. Two of the honorary members, Lord Lister, of London, and Professor Armaur Hansen, of Bergen, had died. The treasurer, Professor Stadelmann, reported that the funds of the society amounted to 280,900 marks, or £14,045. The librarian, Dr. Hans Kohn, said that the reading-room had been visited 10,461 times by members and 11,433 times by their friends. There were 206 medical journals kept in the reading-rooms. The catalogue of the library contains 46,340 volumes, including medical journals and books. During the last year a union of the libraries of nearly all the other important medical societies of Berlin has taken place, the societies having placed their libraries under the control of the Medical Society, paying a certain sum for the use of the reading-room and the salary of the attendants. Considerable sums could be saved because it was no longer necessary for each society individually to subscribe for the same journals. The assembly-room of the society in the Langenbeck House, which is the property of the German Surgical Association and is rented from it, is much too small, and the Medical Society will therefore build new premises under the name of the Virchow House. It is intended to begin the work in October next, and to have it finished in October, 1914. The committee of the Berlin Medical Society was re-elected, Professor Orth being chosen president.

A Medical Excursion to Great Britain.

In connexion with the International Medical Congress in London the central committee for medical excursions will arrange an excursion to England, Scotland, and Ireland. The party will start on August 3rd by special steamer chartered from the Hamburg-America line. They will arrive on August 5th in London, where lodgings will be ready for them at De Keyser's Royal Hotel, Blackfriars. The stay in London will last until August 12th, when they will re-embark on their special steamer and first proceed to Scarborough, where they will arrive on the 13th, leaving the same evening for Leith. The 14th will be spent in visiting Edinburgh, and the 15th in making a trip to the Scotch lakes, including Loch Lomond, Loch Katrine, the Trossachs, and Callander. The next stopping places will be Aberdeen, Stornoway (in the Hebrides), Oban (with a trip to Staffa), Glasgow, Belfast (with a trip to the Giants' Causeway), and Kingstown (with a trip to Dublin). The Channel Islands will be the last British territory visited by the party, which will then go to Rotterdam, from where they will reach Hamburg by steamer on August 28th. The expenses are from 875 to 1400 marks (£43 15*s.* to £70), according to the cabin. No doubt the excursion to Great Britain will be a success, as was the case with the great trip to America last year, arranged also by the central committee for medical excursions on the occasion of the International Congress on Hygiene.

March 31st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Lectures to Students on Questions in Medical Ethics.

THE difficulties of the first few years in practice are in no small degree increased by the problems of medical ethics and economics, which I regret to say are not fully understood by many graduates of our universities. The "Organisation" of the Vienna practitioners has therefore arranged a series of lectures dealing with various subjects necessary to be known by the young practitioner, but especially intended for students of medicine, for it is to them that the Organisation appeals, since they will form the backbone of the medical Organisation in the near future. The most interesting of the lectures, of which some have been already delivered before large audiences, dealt with the relations between the practitioner and (1) the general public, (2) the municipal and state authorities, and (3) public and private corporations, including the sick clubs or Krankenkassen and contract practice generally. A large share of the lectures was allotted to the problems of income taxes and duties, as well as to the position of medical men in forensic cases, a position which is not an enviable one, and it was shown how the new "Penal Code Act" would, if it became law, improve the forensic relations of medicine. As the lectures were well attended the Organisation has decided to continue the experiment.

Sick Clubs and their Medical Officers in Lower Austria.

On Feb. 1st the medical officers of all the sick clubs or Krankenkassen belonging to the various guilds in Lower Austria discontinued, after due notice, their work in the service of these clubs, and restricted themselves to giving medical aid to the men belonging to them at the ordinary fees for private practice. All administrative work such as notification of disease in connexion with contract practice is stopped. The medical officers have given an explanation of their attitude in a pamphlet, addressed to employers and employees alike, setting forth their grievances in six articles, to the following effect: 1. The Union of the Sick Clubs does not recognise the arrangement, as regards contract practice, arrived at between the delegates of medical councils and of the "Committee of the Sick Clubs of Austria" some time ago. 2. The sick clubs want to subject the medical men to the control of non-medical officers. 3. The work of the medical officers is being constantly increased to the detriment of the sick members, whilst their remuneration remains unaltered. The medical officers, therefore, wish to be paid at the rate of so much per patient, and not by a fixed salary without reference to the number of members allotted to each medical officer. 4. The specialists appointed by the "Union" can only be consulted by patients who are not confined to bed, whilst those requiring the advice of specialists, if they cannot go out, must become in-patients in a hospital. 5. The appointment and allotment of the medical officers' districts are matters to be decided not by the local committee of the sick club, but by the "Union." 6. The medical officers object to patients with an income of more than £100 a year being retained on the list of the sick club, and refuse to treat them at the reduced rates of the sick club. For all these reasons the medical officers resigned their appointments at the same time, taking steps to hinder the "Union" from getting other men to take up the work. The conflict has now been going on for two months; the clubs pay their sick members 150 per cent. of their regular sick pay, and provide them with medicine, but not with medical advisers. It appears already that the extra 50 per cent. which the clubs are now paying over and above the regular sick pay is more than they used to spend in the remuneration of the medical officers, and therefore they are trying to find a pacific solution of the difficulty. The profession hopes that the result will be in its favour.

The Winter Term of the Medical Session.

The winter term of the medical session 1912-13 has now terminated, and by this time it is known that the number of medical students has again increased, especially in the German-speaking Universities. In Vienna it has been marked by the erection of the new buildings for anatomical dissection, as well as by the beginning of the Chemical Institute, which will be ready in about a year's time. Since the official commencement of this term in October, 1912, two new hospitals have been established, and four professorships have become vacant, partly through the operation of the age limit of 70 years and partly through death.

March 31st.

MEDICAL MAGISTRATE.—Mr. J. Wheeler-O'Bryen, L.R.C.P. & S.Edin., has been appointed a justice of the peace for the county of London.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The Parliamentary Session.

THE third session of the first Parliament of the Union of South Africa has been opened, but it is not anticipated that it will be of long duration, for the differences between General Botha and General Hertzog on the subject of the relationship of South Africa with the rest of the Empire, which led to the exclusion of General Hertzog from the Cabinet, have caused a widening breach between the two wings of the party in power. It is evident, at any rate after a perusal of the Governor-General's speech at the opening of Parliament, that during this session there will be no legislation of medical interest introduced by the Government. A private measure has, however, been introduced into the Senate which, from the welcome extended to it by Mr. Sauer, the Minister of Native Affairs, on behalf of the Government, should stand a good chance of being passed into law. This is a Bill purporting to deal comprehensively with the question of the protection of child and infant life. In terms of this measure a child includes an infant, and is to be regarded as a person under 16 years of age. The most salutary and severe penalties are prescribed for all forms of cruelty to or for neglect of children. A magistrate, when passing a sentence on or committing for trial any person under the measure who has been charged with neglect of or cruelty to a child, is to be empowered simultaneously, should he think fit, to commit the child to the custody of any person or institution approved of by him that is willing to receive the child. The measure repeals the existing Infant Life Protection Acts of the Transvaal and the Cape and incorporates the provisions of these Acts, or many of them, in a more practical form. It empowers local education authorities to carry out the medical examination of school children, and to deal with children attending school who are in a dirty or verminous condition, or who are suffering from any contagious or infectious disease.

The University Bill.

Mr. Malan, the Minister of Education, has introduced the Bill prepared by him for the establishment of a South African Teaching University at Groot Schûr on a portion of that magnificent estate left by Cecil Rhodes in trust to the nation. The Bill is meeting with a great deal of hostile criticism from the Government back benches. It has not been welcomed very warmly in medical circles, for its provisions are quite inadequate from the point of view of medical education, and it is thought that, although it is generally recognised that the time has not arrived for the establishment of a complete medical school, provision should be made in the Bill to enable such a school to be established whenever it is found practicable in the future. There are a number of objectionable features in the Bill which will doubtless be brought out in debate by the medical members of the House. It is not considered probable that the measure will become law, as a majority of the Government party are strongly opposed to it, but the Bill, if suitably amended, would have gone a long way towards placing higher education generally in South Africa on a much more satisfactory basis than it can ever be under existing conditions. Moreover, there is the danger that the Beit legacy of £500,000 towards the founding of the proposed University may be forfeited unless the scheme is carried out without further delay.

Proposed Restriction of the Cultivation of Dagga.

The Minister of the Interior was recently questioned in the House as to whether the Government intended to take any steps to prohibit the growth and sale of dagga. He stated in reply that the Government was fully alive to the evil effects the consumption of dagga was having upon the coloured and native populations of the Union, but that it was not prepared to take steps in the direction desired for the present. He thought that the whole subject could be best dealt with in the Public Health Act.

Need for Reform in the Administration of the Lunacy Laws.

Nearly three years have elapsed since [illegible] South Africa was established, but no steps app[illegible] been taken to prepare a consolidating Bill [illegible] cy. Consequently the law remains different in each of the four provinces, and the existing laws are mostly antiquated and out of date. All that appears to have been done is to concentrate the administration of these laws under one department in the administrative capital, and this is perhaps responsible for most of the difficulties that would seem to have arisen, as the Department of the Interior is not equipped with the services of an expert adviser, and has to seek advice from the officers in charge of the different asylums whenever it requires guidance, or alternatively to act without obtaining such advice. The result is that no settled policy is being pursued in regard to the administration of the lunacy laws generally, and this is unquestionably responsible for much of the friction and confusion which are occurring at the present time. Moreover, the work of the different asylums is not being properly coördinated, and each asylum is being administered according to the views of the particular medical superintendent in charge thereof. The chaos which now exists was well brought out in the correspondence recently published by a practitioner at Kimberley which has passed between himself and the Minister. At the present time it is certainly the dread of every medical man in practice lest he should be called in to see a patient with acute mental trouble necessitating certification, for, no matter how urgent a case may be, it usually takes weeks, and often months, before authority to send the patient to an asylum is received, and during the interval the practitioner as often as not has the responsibility of looking after the patient under most unsuitable and improper surroundings, or, if the patient is a pauper, he has to hand the case over to the district surgeon to be dealt with where the magistrate thinks best. Apart from the inconvenience of these long delays there can be no question but that at the present time a large number of early mental cases—that would, given proper treatment from the start, stand good chances of recovery—become chronic, because in the absence of suitable accommodation proper treatment cannot be carried out. The matter is really becoming urgent. From time to time grave scandals leak out; questions are occasionally asked in Parliament; the matter is then generally stated to be still under the consideration of the Government, and it then drops until a further scandal occurs.

Robben Island Leper Asylum.

For a long time past dissatisfaction has been expressed with the system of administration at Robben Island, and recently there have been very disquieting rumours. It is suggested that the island is being administered on principles that are radically unsound, and that the sooner the institution is reorganised on modern lines the better it will be for the patients and the community generally. The first step might well be to remove the lunatics and convicts from the island and to use the extra accommodation thus secured for the grading of the patients according to the stage the disease has reached and according to their class in life. Also the administration of the island should be taken out of the hands of a lay Commissioner and the entire island placed under the control of an experienced medical superintendent, who should have full authority to reorganise the institution in accordance with modern ideas. It is understood that a strong movement will be made shortly in Parliament during the present session either for a Select Committee or an outside Commission to inquire into the existing methods of administering the leper asylums in particular, and especially that at Robben Island, and the leprosy laws in South Africa in general. On Jan. 30th the Governor-General and Lady Gladstone, together with the Minister of the Interior, paid an official visit to Robben Island. The object of the visit was to open an exhibition of work by leper patients on the island, but it appears that both the Governor-General and the Minister took the opportunity of inquiring into the methods of administration in vogue.

District Surgeons' Grievances.

There is a growing feeling of discontent amongst the district surgeons of the Union, who are under the administration of the Department of the Interior. Unless allayed by more considerate treatment this discontent is bound to come to a head sooner or later. At [illegible] the district surgeons are still working under [illegible] vincial tariffs that existed prior to U[illegible] certain of the provinces fees had been financial depression. There is considerable disparity between the allowances and the fees paid in the different provinces. Moreover, prior to Union in certain of the provinces district surgeons were under the control of the principal medical officer of health, and were enabled to appeal directly to him against any decision affecting their work given by resident magistrates or other local officials. Since Union the district surgeons have all come under lay control and complaints are general on all sides. The new tariff of witness fees, moreover, hits a district surgeon exceedingly hard. There are many other matters requiring adjustment, and it is to be hoped that the Government will take the opportunity of attending to them when the district surgeons' regulations for the Union come to be prepared.

Feb. 8th.

CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Death of the Empress Dowager.

IN the Palace at Peking early in the morning of Feb. 22nd died the Lung Yü Empress Dowager. Though this event at the present juncture has little political significance, it will be remembered what an important part the late Empress played in shaping recent Chinese history. By abdicating during the Revolution in defiance of the truculent protests of her Manchu kinsmen she certainly saved the country much bloodshed and misery. This act incurred the bitter resentment of her clan—a resentment, it is said, many of them took no pains to conceal. There can be little doubt that the anxiety of the past 18 months materially affected her health. Though it had been known for some time that the Empress Dowager was in failing health her death came as somewhat of a surprise to the general public. It was freely rumoured that Her Majesty had committed suicide, and that she had been moved to this act through chagrin at not being treated with sufficient consideration in the arrangements for the removal of the Court from the eastern to the western part of the Forbidden City. Also it was said that she felt most keenly the lack of respect shown her by the Manchu princes on the occasion of her birthday celebrations, which took place on Feb. 11th. There seems no reason to believe that these reports of suicide had any foundation.

Five days before her death the late Empress Dowager received two American ladies, who were permitted to photograph her and the boy Emperor. The visitors remarked that Her Majesty looked extremely ill and had œdema of the face. Subsequent official reports seem to indicate that renal or cardiac disease was the malady from which the Empress suffered. The following accounts, translated from native newspapers, are of interest as showing purely Chinese methods of treatment. Though a Chinese doctor, named Chüeh Yung-ch'in, who had received a Western education, was sent to the Palace by the President, Yüan Shih-kai, he was not allowed to see the Empress Dowager.

Extract from the newspaper *Ya-hsi-ya Pao* of Feb. 24th:—

The Imperial doctor, Ch'ang Tsuan-Yüan, reported that on Dec. 28th of last year the Empress Dowager showed symptoms of swelling, which started at the ankles and gradually rose till it reached the hips. It was not till Jan. 10th that Her Majesty summoned doctors of the Imperial Medical Board. Dr. Ch'ang went in to treat the case. His opinion was that the disease was of the nature of œdema. He ordered *wu-fu san* (a powder made from several kinds of *pachyma cocos*, a fungus which grows upon the roots of firs) as a diuretic, without successful result. Then stronger medicines were administered—viz., *ling-shu* (roots of species of *atractylodes*), *chih-tsao* (*hovenia dulcis*), and *chiu-chün* (matured native wine), which together compose a strong diuretic. Fluid was evacuated both from the bowels and by the urine, and the swelling subsided. Ginseng was administered both as a tonic and in order to help digestion. On account of indiscretions in diet œdema again appeared on Feb. 1st, and became more extensive than it was previously. In the space of one night the swelling reached as high as the hips. On Feb. 2nd Dr. Ch'ang was again summoned to the Palace and made use of the old prescription with a few additions—viz., of *ting-li* (seeds of *draba nemoralis*, which resembles mustard) and of ginseng. Fluid was again evacuated, but the stomach had become very weak, and the doctor ordered such tonics as *ssŭ-chün-tzŭ-t'ang* (a decoction composed of ginseng, *atractylis ovata*, *pachyma cocos*, dried licorice root, ginger, and dates), *i-i* (c [illegible] (the bean *dolichos lablab*), in order to [illegible] Feb. 5th another dose of diuretic medicin [illegible] the swelling had totally subsided, and two [illegible] had disappeared.

It will be remembered that Feb. 15th and 16th were the days on which the birthday celebrations took place, and Her Majesty came out to the audience hall to receive congratulations. No doubt she was much fatigued after these exertions, and on Feb. 17th she felt cold sensations in her limbs. Dr. Ch'ang prescribed some diaphoretics, such as *kuei-chih* (tips of young branches of *cinnamomum cassia*), to cause profuse perspiration. The disease was alleviated, but at 10 o'clock in the morning of Feb. 21st a violent chill supervened and the condition became very critical. Dr. Ch'ang ordered the following medicines: *kua-lou* (*tricosanthes multiloba*, a kind of bryony), *pan-hsia* (*pinellia tuberifera*), *chü-hung* (orange-peel), and *chu-li* (bamboo sap), but without any effect. The breathing became very laboured and the pulse was intermittent. Then Dr. Ch'ang administered some medicine called "Powder for Stimulating the Pulse," to which were added a few other ingredients, such as bamboo sap, orange-peel, and ginger juice. After taking this mixture Her Majesty was not much relieved, so Dr. Tsao Yüan-sun was summoned. Dr. Tsao changed the prescription and used *shih hu* (yellow stalks of an epiphyte, *dendrobium ceraja*, which grows on stones), *shih-kao* (calcium sulphate), *chên-chu* (*phyllanthus urinaria*), *mou-li* (shells of the rock-oyster), *lung-tao* (fossil bones), *fu-shên* (*pachyma cocos*, a fungus that grows on the roots of firs), *kua-lou* (seeds of a kind of bryony), bamboo juice, and orange-peel. However, all these had no beneficial effect, and the Empress Dowager died at 2 A.M. on Feb. 22nd.

Another paper, the *Kuo-chüan Pao* of Feb. 23rd, published a long editorial discussing the cause of the Empress Dowager's death. After referring to the annoyance caused Her Majesty by the insolent behaviour of the Manchu princes and of some of the Imperial concubines, it dwelt upon the Empress's disappointment that after a year of Republican government the country was still in such an unsettled state. None of the various possible factors, however, were considered so likely to have brought about the fatal termination to the Empress's illness as the treatment carried out by the Court physicians. As the writer remarked, the drugs used were numerous, and the prescriptions ordered by the various doctors were not harmonious in their actions.

The writer continued: "We have contrived to get copies of prescriptions from the Imperial household. The first one is written by Dr. Tsao, who respectfully requested permission to feel the Imperial pulse, and gave his opinion as follows: 'The three sections of the left hand pulse are slow and weak; the section an inch above the wrist on the right side has but little strength. Breathing is extremely difficult and she cannot lie down. Phlegm is continually rising. Her strength is exhausted and perspiration is too profuse. The dorsum of the tongue is black as charcoal, but on each side the surface is natural. Her strength is rising up and the central part of the body is left exhausted. I have grave fears that œdema of the lungs will be so extensive that suffocation will result. I propose to imitate the methods followed by the eminent authority Man-chien, and further, attempt to make my prescription according to the principles expounded by the Taoist priest Sun.'"

Here followed a copy of Dr. Tsao's prescription, containing 13 ingredients, most of which have been already mentioned above.

Peking, March 10th.

Obituary.

ALFRED LEWIS GALABIN, M.D. CANTAB., F.R.C.P. LOND.,

CONSULTING OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL;
LATE FELLOW OF TRINITY COLLEGE, CAMBRIDGE.

WE regret to announce the death of the well-known obstetric physician and author, Dr. Alfred Lewis Galabin, which occurred at the age of 70 from pneumonia, after only five days' illness, on March 25th, at his residence at Bishopsteignton, Devon.

Alfred Lewis Galabin was born on Jan. 10th, 1843, and received his education at Marlborough and at Trinity College, Cambridge, where he was a foundation scholar and also Wrangham gold medallist. He graduated at Cambridge in 1866 as a double first in classics and mathematics, which was already becoming a rare distinction. He was seventeenth wrangler and also bracketed eighth in the classical tripos of the same year, and was duly elected a Fellow of his College. Having decided to enter the medical profession, he proceeded to the medical school at Guy's Hospital.

He took the Membership of the Royal College of Surgeons of England in 1872, and in the following year graduated as M.D. at Cambridge. He took the Membership of the Royal College of Physicians of London in 1874. In that year he was appointed lecturer on clinical midwifery, in 1875 obstetric assistant physician, and in 1876 lecturer on diseases of women in Guy's Hospital. He became a Fellow of the

Royal College of Physicians of London in 1878, and 20 years later served on the Council In 1884 he was appointed full obstetric physician and in 1887 lecturer on midwifery, all of which posts he held until he passed on to the consulting staff at Guy's in 1903 He was also for a time assistant physician to the Hospital for Children, Great Ormond street

A testimony to the range and accuracy of his professional learning, as well as to his academic distinction, may be *found in the number of examinerships which he held* In the "eighties" and "nineties" Dr Galabin was several times examiner to the Royal College of Physicians He was also examiner in obstetrics at the Universities of Oxford, Cambridge, and London He held most of the offices in the Obstetrical Society of London, and was president in 1899-90

In 1873 Dr Galabin published a small work on "The Connection of Bright's Disease with Changes in the Vascular System," and several of his early communications to the medical press dealt with the circulatory system His first work on the subject with which his career was subsequently identified was his "Students' Guide to the Diseases of Women," published in 1879 Terse and clear in style and pleasant to read, it bore evidence of erudition, careful observation, and sound judgment, and in many places, particularly in regard to the pathology and morbid anatomy of the conditions dealt with, displayed its foundation of original work It was, in fact, for its size, the best and most complete work on the subject The sixth edition, which appeared in 1903, was substantially a new book The author's extensive practical experience and his intimate acquaintance with the special needs of students, gained in a long association with them both as teacher and examiner, fitted him peculiarly for his task, and the book displayed one of his marked personal characteristics, his well balanced judgment enabling him to present fairly both sides of a debatable point In 1886 was published his "Manual of Midwifery," which also speedily became deservedly popular and was given first place among the treatises on that subject in the list of text books for students issued in THE LANCET, which in those days was published every year in the Students' Number This book also reached a sixth edition in 1903 In 1910 a seventh edition, written in collaboration with Dr G F Blacker, appeared under the title of "The Practice of Midwifery" It was greatly enlarged, brought well up to date and it is widely regarded as one of the best text books on the subject yet published by English authors Galabin's knowledge of mathematics enabled him to demonstrate and prove many points which were often obscure in the works of other obstetricians, and although his tendency to resort to mathematical proofs in his books did not always appeal to student readers, yet it gave a real and enduring value to his writings, more particularly those dealing with the mechanism of labour and the development of the pelvis He was a clear thinker and speaker, and on the many occasions in which he took part in discussions at the various societies he was always listened to with attention and respect If he made no important addition to our knowledge of midwifery, his writings and teaching influenced large numbers of students, and his "Manual of Midwifery" remained without a serious *rival as an authoritative text-book for a number of years*

Dr Galabin was not a prolific contributor to the medical press, most of his communications being made to various societies and appearing in their Transactions, what he did write was characterised by good judgment and balance For some years he was the editor of the *Obstetrical Journal of Great Britain and Ireland*, and in this, among other papers, he wrote on the Action of the Midwifery Forceps, the Effect of the Frequent and Early Use of the Midwifery Forceps upon the Fœtal and Maternal Mortality, the Occurrence in Normal Labour of Obliquity of the Fœtal Head, the Choice of the Leg which should be Seized in Version; on a case of Extra uterine Fœtation not Primarily Tubal (Primary Abdominal Fœtation), and on a New Form of Axis Traction Forceps His contributions to the discussions on the Production of the Shape of the Oblique Pelvis, on the Obstetrics of the Kyphotic Pelvis, and on Scarlatina during Pregnancy also were published in this journal Among his other contributions to medical literature many were of considerable value, and mention may be made of his report on Puerperal Pyrexia, published in 1884, in the Collective Investigation Record of the British Medical Association

Mr R Clement Lucas writes:—"The death of Dr Alfred Galabin removes one more from that inner circle of intimate friends formed during my student days and firmly maintained throughout life A true and always loyal friend was Galabin How well I remember his arrival at Guy's Hospital, with his extraordinary reputation as a 'double first' from Cambridge, and with what critical eyes we scanned the new recruit to trace wherein his great powers lay A *pale, black haired, slight, delicate, spectacled man, clearly* no athlete, he was probably reared with books as his early companions, at a time when many boys are demonstrating their evolution by violent sports A closer inspection showed a face of the highest intelligence, calm and gentle, on which boisterous mirth would never find even a temporary resting-place, though under amusement the features would relax into a very sweet smile His dignified integrity of character and sound judgment adorned the branch of the profession which he chose, and which in a previous generation had contained occasionally members not unjustly subjected to adverse criticism Dr Galabin's manner, no less than his obvious code, at once silenced the vulgarity that was two generations ago too frequent in the chamber of inheritance He was universally trusted At the time of Galabin's appointment to the post of obstetric physician at Guy's Hospital this officer was limited to the operations of labour, whilst ovariotomy and hysterectomy were performed by the surgeons About this time several physicians engaged in this special department elsewhere began to extend their sphere to the uterine appendages, and even further in the abdomen, and claimed the title of gynæcologists Galabin pressed this claim with a quiet persistence at Guy's, and though it was at first objected that obstetricians were not trained surgeons, permission was eventually given to perform the operation of ovariotomy, and this gradually led to the withdrawal of such cases from the general wards and to the appointment of obstetricians with a surgical training As a teacher Dr Galabin was too undemonstrative to be popular with the bulk of students and his lectures, carefully prepared and full of good material, lost weight by being read without emphasis, but he was universally esteemed for his exact knowledge, and those who wanted to learn knew the value of his teaching His high mathematical knowledge obtained useful employment in the mechanics of labour, which found expression in his book, but the average students dreaded lest this mathematical knowledge would be expected of them when he was examiner From what I have said it will be gathered that Dr Galabin was valued most by those who knew him best He was a man of the highest intelligence, kind hearted, and of the most amiable disposition, always a friend in trouble or difficulty, and universally respected in his profession"

THE NATIONAL INSURANCE ACT.

THE Insurance Commissioners have issued a revised form of Agreement (Form Med 29) between medical practitioners and Insurance Committees This Agreement *which will take effect on April 14th, 1913, refers only to the* capitation method of payment The wording of the terms and conditions of service differs in various respects from that in the former Agreement, and the schedules have been recast

NATIONAL INSURANCE PRACTITIONERS' ASSOCIATION.

A largely attended meeting of medical practitioners, convened by the National Insurance Practitioners' Association, was held on March 27th at the Westminster Palace Hotel, London, Dr Lauriston E Shaw being in the chair The meeting expressed its satisfaction at the decision of the Insurance Commissioners that no further wholesale "signing on" of insured persons would be required, and urged practitioners to give the suggested card system a careful and thorough trial The question of the limitation of lists was vigorously discussed, and it was resolved that further experience must be gained before it could be decided *how* many insured persons each medical man could treat The opinion was emphasised that at the termination of the present quarter all moneys for medical benefit should be allotted to each practitioner then on the panel in proportion to the number of insured persons on his list, regard being had to the date at to medical officers of health employed by local authorities and for contributions towards such allowances by those officers. Statutory provision of a similar nature has been alread made for Poor-law medical officers by the Poor-law Officers' Superannuation Act, 1896, and for the officers of asylums by the Asylum Officers' Superannuation Act, 1909.

The Bill contains 21 clauses, many of which are for the purposes of *machinery*.

Clause 1 sets out the title of officers of health to superannuation allowances in the following terms :—

"Subject to the provisions of this Act, every officer of health appointed by a local authority, whether before or after the commencement of this Act, who either (1) shall complete an aggregate service of 35 years ; or (2) shall become incapable of discharging the duties of his office with efficiency by reason of permanent infirmity of mind or body not arising from his own misconduct ; or (3) shall attain the full age of 60 years, shall be entitled on resigning or otherwise ceasing to hold his office to receive during life a superannuation allowance according to the scale laid down in this Act. Where an officer of health has attained the age of 65 years, and the local authority under whom he shall then hold office are of opinion that it would be expedient in the interests of the public service that he should cease to hold office, it shall be competent for that local authority to require him to retire upon payment to him of the superannuation allowance to which he may be entitled under this Act."

Clause 3 contains the scale of superannuation allowances. It provides that "an officer of health who has served for ten years but less than eleven years shall be entitled to an annual allowance equal to fifteen-sixtieths of the average amount of his salary or emoluments during the five years ending on the quarter day which immediately precedes the day on which he ceases to hold office, with the addition of one-sixtieth of such average amount for every additional completed year of service until the completion of a period of service of 35 years when a maximum allowance of forty-sixtieths shall be granted."

Clause 14 fixes the scale of contributions. It is as follows :—

"The percentage amounts to be deducted annually for the purposes of this Act shall be as follows :—

In the case of officers with less than five years' service at or appointed after the commencement of this Act, two per centum of the salary for each year ;

In the case of officers with more than five and less than 15 years' service at the commencement of this Act, two-and-a-half per centum of the salary for each year ;

In the case of officers with more than 15 years' service at the commencement of this Act, three per centum of the salary for each year."

Milk and Dairies Bill.

Mr. BURNS, the President of the Local Government Board, has introduced in the House of Commons a Bill "to make better provision with respect to the sale of milk and the regulation of dairies." It has been read a first time.

In a Memorandum the objects of the Milk and Dairies Bill are summarised. The principal of these are to provide for (1) the more effective registration of dairies and dairymen ; (2) the inspection of dairies and the examination of cows therein and the examination of milk ; (3) the prohibition of the supply of milk from a dairy where such a supply has caused, or would be likely to cause, infectious diseases, including tuberculosis ; (4) the prevention of the sale of tuberculous milk ; (5) the regulation of the importation of milk so as to prevent danger to public health arising therefrom ; (6) the issue of regulations for securing the supply of pure and wholesome milk ; and (7) the establishment by local authorities in populous places of milk depôts for the sale of milk specially prepared for infants.

As the memorandum goes on to state, the provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts and the orders made thereunder. The provisions as to the inspection of dairies and the prohibition of the supply of milk are based on the provisions of the Public Health (Scotland) Act, 1897. The clause as to the prohibition of the sale of tuberculous milk is taken from the model milk clauses, which have been incorporated in many local Acts, but the scope of the enactment is somewhat extended. The Board of Agriculture and Fisheries have issued an order under the Diseases of Animals Act, 1894, dealing with tuberculous cows, and providing for the payment of compensation in cases of slaughter. The Treasury are prepared, subject to the assent of Parliament, to sanction the payment from the Exchequer of one-half of the net amount paid by way of compensation for a period of five years.

Milk and Dairies (Scotland) Bill.

Mr. MCKINNON WOOD, the Secretary for Scotland, has presented a Bill in the House of Commons "to ensure the purity of milk supplies and to regulate dairies in Scotland." It has been read a first time.

Select Committee on Patent Medicines.

The Select Committee of the House of Commons on Patent Medicines resumed on Thursday, March 27th, the hearing of evidence from the standpoint of owners of proprietary articles.

Elementary Education (Defective and Epileptic Children) Bill.

A Bill has been introduced into the House of Commons by Mr. J. PEASE, President of the Board of Education, laying on local educatio authorities the duty to provide for the education of mentally defectiv children. It has been read a first time.

Deaths Registration and Burials Bill.

Amongst the Bills introduced in the House of Commons recently one "to amend the law relating to the registration of deaths and burials." It was presented by Mr. GEORGE GREENWOOD.

General Medical Council.

The accounts of the General Medical Council and branch councils an of the Dental Registration Fund have been laid on the table of th House of Commons.

The Mental Deficiency Bill.

The Mental Deficiency Bill which was issued on Monday last is substantially the same as the Bill which the Government dropped las session from its programme of measures, owing, it was said, to the shortage of Parliamentary time. There has been considerable rearrangement of the clauses and some interesting omissions. For example Part I. of the original Bill, which dealt with the central and loca authority, has now become Part II. The Board of Control is to be constituted as follows: there will be 15 Commissioners, of whom not mor than 12 should be paid, and of those paid four should be legal and fou medical, and at least one of the paid and one of the unpaid Commissioners shall be a woman.

Part II., describing the methods of dealing with the mental defective has now become Part I., and the first clause of the new Bill define defectives as follows :—

(*a*) *Idiots*; *that is to say*, persons so deeply defective in mind fro birth or from an early age as to be unable to guard themselve against common physical dangers ;

(*b*) Imbeciles ; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness no amounting to idiocy, yet so pronounced that they are incapable of managing themselves or their affairs, or, in the case of children, of being taught to do so ;

(*c*) Feeble-minded persons ; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness not amounting to imbecility, yet so pronounced tha they require care, supervision, and control for their own protection or for the protection of others, or, in the case o children, are incapable of receiving proper benefit from the instruction in ordinary schools ;

(*d*) Moral imbeciles ; that is to say, persons who from an early age display some permanent mental defect coupled with strong vicious or criminal propensities on which punishment has little or no deterrent effect.

Clause 50 of the original Bill, which prohibited marriage with a defective, is now omitted. The new Bill makes no provision for Scotland, which division of the kingdom will be dealt with by separate legislation.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 26TH.

London Water-supply.

Sir JOHN LONSDALE asked the President of the Local Government Board whether his attention had been called to the reported contamination of part of the London water-supply; and whether he could give any information on the subject to allay public apprehension.—Mr. BURNS replied: My attention has been drawn to the matter referred to, and I have been in communication with the Metropolitan Water Board, who have been investigating it since the first complaints were received. The unpleasant taste which has been noticed in the water is due to the decay of algæ, but I am glad to be able to state that it is not in any way injurious to health. The source of the trouble having been discovered, steps have, I understand, been taken to remove the ground of complaint.

Medical Benefit and Insured Persons on Holiday.

Mr. RONALD MCNEILL asked the Secretary to the Treasury what arrangement had been made for providing medical benefit for insured persons who might become entitled to it while absent from their usual places of residence for holidays or otherwise.—Mr. MASTERMAN answered: The question is being brought before the Advisory Committee to-morrow. I have nothing to add in the meantime to the previous answers which I have given on this subject.

Mr. RONALD MCNEILL: Will the Regulations be issued as soon as possible?—Mr. MASTERMAN: There are Regulations issued and provision is being made, but as there is some criticism of the present provisions the whole matter is being brought before the Advisory Committee, which represents the doctors and the Approved Societies. I recognise as much as the honourable gentleman the urgency of the question.

Small-pox in the Navy.

Mr. MACNAMARA (Parliamentary Secretary to the Admiralty) informed Mr. BENTHAM that no small-pox cases had recently been reported as having occurred amongst the crews of any of His Majesty's ships at Devonport other than the *Conqueror*.

Colour Vision Tests in the Mercantile Marine.

Lord HUGH CECIL asked the Parliamentary Secretary to the Board of Trade whether the tests for defective colour vision approved by the Board of Trade differed from those approved by the Admiralty, and if so, whether the Board of Trade, in view of recent scientific investigation and discussion, intended to adopt the tests now approved by the Admiralty.—Mr. J. M. ROBERTSON said in reply: The colour vision tests in force for the mercantile marine are not identical with those approved by the Admiralty. A *Departmental Committee, including a number of eminent scientific men, has recently considered the sight tests for the mercantile marine, and the recommendations of the committee* have been generally adopted. The new tests based on their recom-

opinions.

School Clinics.

The Grants to Scottish Universities.

Answering Mr. JAMES HOGGE, Mr. MASTERMAN said: It is proposed to pay the full grant for this year to all the Scottish universities, subject in the case of Edinburgh University to the appointment of a committee (as has already been done by Glasgow University) to consider the establishment of an inclusive fee in medicine.

Sanatorium Benefit in the Lindsey Division.

Mr. WEIGALL asked the Secretary to the Treasury how many sanatoria there were in the Lindsey area of Lincolnshire, and how many consumptive cases had received treatment in this area up to March 1st last.—Mr. MASTERMAN wrote in reply: Up to March 1st 48 applicants had received sanatorium benefit from the Lindsey Insurance Committee. Twenty-one of these cases were sent to sanatoria and 27 received domiciliary treatment. There are no approved sanatoria actually in the Lindsey area, but the Committee have made arrangements with sanatoria in Lincoln, Withersea, Horsforth, and Ipswich.

Imported Milk.

In reply to Mr. STANIER, Mr. BURNS wrote: In no case was any fresh imported milk during January and February declared to be unfit for human consumption.

THURSDAY, MARCH 27TH.

Ireland and the Mental Deficiency Bill.

Scottish Clerks' Association and Medical Benefit.

Mr. MACCALLUM SCOTT asked the Secretary to the Treasury whether he was aware that for ten years before the commencement of the National Insurance Act the Scottish Clerks' Association had a system of medical benefit whereby members called in their own

their members. It is primarily the duty of the Insurance Committees concerned to consider whether, in view of these arrangements and of any other local circumstances, members of the association could

Udal Torre Sanatorium.

Lord NINIAN CRICHTON-STUART asked the Secretary to the Treasury whether he was aware that complaints were being made as to the daily routine, the quality of the food, the small amount of food provided for each patient, and the general treatment of patients at the Udal Torre sanatorium in Devonshire; whether this was as contemplated by the

number of patients, on hearing that certain complaints had been made, volunteered the statement that they had no similar complaint, and that in their opinion everything possible was being done for their benefit.

Medical Benefit in West Hougham.

MONDAY, MARCH 31ST.

Contributions to Hospitals and the National Insurance Act.

Sir J. D. REES asked the Secretary to the Treasury whether he was aware that *the Saturday collections for Nottingham Hospital were* £1600 less than those of the previous year; that the deficiency was due to the unwillingness of subscribers to continue their subscriptions since

contemplated.

Medical Aid Association.

Sir J. D. REES asked the Secretary to the Treasury whether he was aware that the Friendly Societies operating in the Heanor, Langley

Maternity Benefit in Scotland.

In answer to Mr WATT, Mr. MASTERMAN said: No full information is yet available as to the different forms in which the Approved Societies in Scotland are (within the discretion allowed to them under the Act) administering maternity benefit, but I am informed by the Insurance Commissioners that some of them are giving a part of the benefit otherwise than in cash—e.g., paying a doctor or providing necessities required in connexion with the confinement.

of the induced self-deception and dishonesty that almost invariably take possession of even the naturally most honourable characters under the insidious deteriorating effects of the drug, so that rigid external control is practically an essential for the successful treatment of the habit. He speaks favourably of the homes of the Church of England Temperance Society, by which society (4, Sanctuary, Westminster) the pamphlet is published.

THE NEW STANDARD DICTIONARY.

In a few weeks Messrs. Funk and Wagnalls will be issuing a new edition of the Standard Encyclopædic Dictionary, over which, it is stated, £300,000 have been spent. More than 300 specialists and editors have been engaged for some years in its preparation, among whom are Lord Avebury, for financial terms; Sir George Birdwood, M.D., Indian terms; Admiral Sir Cyprian Bridge, naval; Colonel Sir David Bruce, M.D., tropical diseases; Sir James Crichton-Browne, medical; Earl Roberts, military; Professor J. P. Mahaffy, classical; and other well-known names, British and foreign. The dictionary will define over 450,000 terms of all kinds. The 7000 black-and-white illustrations will be supplemented by a series of colour plates. A noteworthy new feature is that whereby when quotations are used to establish some point of definition or pronunciation the exact reference is given.

150,000 MICROSCOPES.

The optical and mechanical engineering works of Ernst Leitz, of Wetzlar, have recently completed their 150,000th compound microscope. This instrument has been presented to Professor Ehrlich, of Frankfort-on-Main. The 100,000th Leitz microscope was presented to the late Robert Koch.

◆

G. V.—We understand that under the Local Government Board General Order of Dec. 19th, 1912, medical practitioners notifying cases of pulmonary tuberculosis, as required by Article V. of the Order, are entitled to payment of a fee for each notification of 2s. 6*d.* if it is given by the medical man in the capacity of private practitioner and 1s. if it is given in his capacity as medical officer of a hospital or Poor-law institution or as a district medical officer. It is not necessary for the medical practitioner to send any account for these fees, which become payable by the local authority at the end of the quarter. The procedure and the fees are identical in the case of insured and non-insured persons, no distinction having been made in the Order under which the payment is authorised.

Dr. J. B. Hurry (*Westfield, Reading*) would be glad to know where the engraving of the late Lord Lister which was published a few years ago can be obtained.

Communications not noticed in our present issue will receive attention in our next.

The following Congresses, Conferences, and Exhibitions are announced for 1913:—

April 3rd–9th (London).—International Congress of Historical Studies.
,, 6th–12th.—Health Week.
,, 15th–18th (Wiesbaden).—Congress of Internal Medicine.
,, 22nd–25th (London L.C.C. Technical Institute, Vincent-square).—Annual Nursing and Midwifery Conference.
,, 26th (Ghent) (opens).—International Exhibition.
May 15th–18th (Paris).—Twenty-first Annual Congress of the Royal Institute of Public Health.
May–October (Leipzig).—First International Building Exhibition.
June 24th–27th (London, Ontario).—Canadian Medical Association.
July 7th–12th (Exeter).—Twenty-eighth Congress of the Royal Sanitary Institute.
,, 16th–18th (Oxford, Keble College).—Oxford Ophthalmological Congress.
,, 22nd–25th (Brighton).—Eighty-first Annual Meeting of the British Medical Association.
Aug. 4th and 5th (London, Caxton Hall).—English-speaking Conference on Infant Mortality.
,, 6th–12th.—(London).—Seventeenth International Congress of Medicine.
,, 20th–26th (Ghent).—Third International Congress of Neurology and Psychiatry.
Sept. 2nd–6th (Groningen).—International Physiological Congress.
,, 9th–13th (Vienna).—Second International Congress of Life Saving and Prevention of Accidents.
,, 10th–17th (Birmingham).—British Association.
,, 22nd–28th (Milan).—Fourteenth International Anti-alcoholic Congress.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(London, Earl's Court).—Imperial Services Exhibition.
(Chicago).—Congress of the International Association of Refrigeration.
(Washington).—Congress of American Physicians and Surgeons.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed 'To the Sub Editor"

Letters relating to the publication sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed 'London County and Westminster Bank, Covent Garden Branch') should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

An Address

ON

SOME GENERAL CONSIDERATIONS REGARDING THE RELATIONS OF THE MEDICAL PROFESSION AND THE PUBLIC.

Delivered to the Ulster Medical Society on March 6th, 1913,

By JAMES ALEXANDER LINDSAY, M.D.
R.U.I., F.R.C.P. Lond.
PROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY, BELFAST.

Gentlemen,—Our secretary h[illegible] task of submitting to you so[illegible] regarding the relations of the [illegible] public, a task which I would not have ventured to undertake unsolicited, and to which I address myself with unfeigned diffidence. I am informed that some of our members think that the present time of conflict and uncertainty, when our profession is the object of so much ill-informed and ungenerous criticism, is a suitable opportunity for reconsidering our responsibilities, duties, and privileges. It is sometimes salutary to hark back to first principles and to inquire what help they afford in dealing with the difficulties of the hour.

The National Insurance Act.

The Insurance Act, which is now the law of the land, and not likely to be abrogated, has [illegible] share of infantile disorders. [illegible] thoroughly healthy maturity I[illegible] Experience upon the point in Germany is not altogether reassuring. But one thing is certain. The Insurance Act is bound to have far-reaching effects for good or for ill upon the status, dignity, and usefulness of the medical *profession.* A large majority of our brethren have become, or are about to become, State servants, in receipt of State pay, and owing obligations to the State. In future they will have to acknowledge a threefold obligation—to their patients, an obligation which is primary and fundamental for us all; to their profession and their medical brethren; and to the State in its corporate capacity. The controversies which have raged round the Insurance Act have been to many of us painful and disquieting. They have too often shown a singular lack of appreciation of profession[illegible] and a niggardly recognitio[illegible] The work of safeguarding [illegible] battle against disease—a work certainly as honourable and indispensable as that of administering our laws or providing for the national safety—has been the object of much misrepresentation and ill-timed satire. Our critics have not always stopped to inquire whether their own contribution to the labours of the nation will bear comparison with that which they have belittled and impugned. Politicians have argued as if you could contract for medical service as you contract for the supply of milk or potatoes, forgetting that the one indispensable thing in a medical contract is to secure the good-will of the doctor and to have an assurance that the best that is in him, the best of his knowledge, energy, and skill, will be ungrudgingly devoted to his patients' welfare. A reluctant medical service will always be a bad medical service. Men smarting under the sense of compulsion or injustice cannot in the nature of things be expected to give their best to duties which are believed to involve unnecessary hardship. I do not affirm that all sense of injustice may not yet be removed, but I do confidently affirm that if the State wishes to be well served by the doctors it must treat them with respect and consideration, and not only secure but deserve their cordial coöperation.

Unqualified Medical Practice.

Another disquieting sign of these days was afforded by a recent controversy in the columns of the *Times* on the subject of quackery. In the course of that correspondence it was laid down by various authorities, more or less eminent, that if anyone could prove his capacity to cure, whether as a bone-setter or the possessor of some new drug, he had as good a right to practise medicine as any legally qualified practitioner, and that it was persecution and rank professional jealousy for the medical profession to refuse recognition and professional courtesies to such persons. The reply to this contention is very simple. The possession of a medical qualification is a guarantee that its possessor has spent several years in the studies of his profession, that he has some knowledge of the ancillary sciences, that his acquaintance with anatomy, physiology, chemistry, and materia medica will go far to preserve him from elementary errors, and that he has observed disease in hospital sufficiently long and sufficiently well to have a fair knowledge of the true nature, the probable course, the dangers, and the suitable management of the maladies entrusted to his care. Under none of these heads has the public any guarantee as regards the quack. Natural dexterity or happy chance may enable him to reduce a dislocation or set a fracture which has baffled the surgeon, but he is even more likely to do harm. He may make a lucky hit in the field of medicine, but as he is ignorant of pathology, and his diagnosis is mainly guesswork, it is evident that his intervention may be fraught with serious risk to the patient. The British laws are very tolerant of irregular medical practice, much more tolerant than the laws of most civilised countries. In the field of medical practice there still lingers in the public mind something of the *laisser-faire* spirit of the now discredited Manchester school of politicians. *Caveat emptor* is a favourite maxim with the British people. The vague idea that, as we are a free nation, it is an infringement of public liberty to check irregular medical practice is widespread. But it is a shallow and short-sighted conception. The State which protects us against adulterated foods has no right to permit the sale of powerful and often poisonous drugs under some [illegible] civilised states and insist that the public shall know what it is buying.

It is not, however, to such obvious matters that I conceive I am requested to direct your attention, but rather to some of those ultimate principles which must regulate the relations of our profession to the public, if those relations are to be mutually satisfactory, if the prevention and cure of disease are to be successfully promoted, and if the interests of medical science are to be conserved. Just as the wise administration of the law is a matter not of mere professional interest but of fundamental national importance, so the cultivation and successful practice of medical science is a matter which concerns not the medical profession only, not our nation only, but our common humanity. For life, work, and happiness nothing is more essential than health. No interest is more vital to the State than the physical well-being of its inhabitants. If the practice of medicine is not wisely regulated, if it is not accorded due recognition and adequate reward, if it is harassed by unwise legislation, if it ceases to attract the best minds to its service, it is the public, the nation, which in the long run will suffer.

A Glance at the History of Medicine.

It may not be amiss to begin our survey by a glance at the past. The history of medicine, which is far too little studied, is full of instruction for us. We are apt to underrate the achievements of our remote predecessors in the field of medicine, and to imagine that where there was little science there could be no successful art. But the history of medicine in *Mesopotamia, in Persia, in Egypt, and, above all, in Greece,* shows with what zeal and insight the phenomena of disease were studied in early ages, and how many wise and successful methods of treatment were in operation. The *history of medicine* may be compared to two parallel currents. One current begins in magic and sorcery, passes through priestcraft, and ends in science. The other current is that of empiricism, which flows parallel to the first current, and sometimes rivals or surpasses it in volume and in strength. Primitive man attributed disease to demonic power; treatment was conceived as a contest between opponents, each [illegible] wielding the weapons of sorce[illegible] by magic. In this stage of [illegible] and the witch doctor represe[illegible] later stage the conceptions of [illegible] tion, fumigation, fasting, &c., make their appearance, and the palliated, to be sure, by well-adjusted belts, and the steady advance in bulk be checked to some extent. But no form of belt with which I am acquainted will prevent a large ventral or umbilical hernia from escaping from the ring. Belts may help a patient who is debarred by some grave ailment from undergoing an operation, but only by controlling the weight of the protrusion, and even that only imperfectly. In the future it is to be hoped that fewer and fewer people will be allowed to acquire large herniæ and to drift into middle life with them without some well considered attempt being made to cure them by operation.

It must not be forgotten that unless they are relieved of their herniæ they are constantly subjected to risks of several kinds. Among these may be mentioned strangulation, incarceration following on constipation, and all the evil results to general health which depend on curtailed active exercise. Illustrations of this are only too frequent in all walks of life. And these risks and disabilities have to be balanced against those of operations for their relief. The latter, real enough in former years, are apt to be too much emphasised at the present day, and one has seen many cases restored to activity and excellent health who have been operated on in the face of chronic and even acute bronchitis, of alcoholism, albuminuria, and glycosuria. The fact is that each case must be considered for itself and the *pros* and *cons* carefully balanced before a final decision can be come to. In practice some of the apparently least favourable cases have turned out the best in the end. Experience alone can guide us in our choice. Let us take an illustration or two.

Successful Operations in Unfavourable Cases.

I was called some time ago to the country by Dr. C. R. A. Sutton, of Sidcup, to see a very stout lady, weighing 18 st., who had had a large umbilical hernia for several years. A few months before she had had a "stroke," with left hemiplegia, which was still present. A day or two before I saw her the left side of the skin over the sac had become gangrenous and had given way shortly before my visit, exposing the contents, which consisted of small intestine. As the surface of the skin around the sac was eczematous and very foul, boracic fomentations were applied over all for 24 hours. Then, as the patient had bronchitis, I operated under local analgesia. The whole of the gangrenous skin and sac were excised and the peritoneum stitched up. The rectus sheath on each side was split up on its inner border from above downwards and the proximal borders of each united in the middle line over the peritoneal suture. A wire filigree was then inserted under the outer edges of the rectal sheaths on either side, and these were stitched over the network. Skin suture followed. Primary union was found to have taken place at the first dressing. Perfect recovery followed, and the patient was able to travel to Scotland not long after and remains quite well now, as Dr. Sutton kindly reports. More unfavourable conditions could hardly be thought of in view of the hemiplegia, the bronchitis, and a gangrenous sac. It may be said that here there was no choice but to let the patient die, and therefore the operation was quite justifiable. That is so, but the case proves that very unfavourable conditions do not always render an operation hopeless.

Another case illustrates the same thing. A gentleman aged 72, formerly of sporting habits, had been for a long time prevented from taking any active exercise by a very large right inguinal hernia, and he expressed himself as very miserable. His general condition was not good in several respects. He was described by his family adviser, Dr. J. F. Macpherson, of Basingstoke, as "chesty," as having at times albumin in his urine, and as living very well. Every kind of truss had failed to control the hernia. I was asked to operate as he was determined to face the risks put before him to obtain relief. Spinal analgesia was considered the safest method of relieving pain and obtaining perfect relaxation which was necessary on account of the size of the protrusion and the wide ring to be closed. The ordinary Bassini operation was done under the most ideal conditions as to relaxation and quiet breathing and cheerfulness during operation, and convalescence was absolutely uninterrupted; not a hitch occurred from beginning to end. I have heard of him within the last few days as enjoying his restored activity during the six months which have elapsed since the operation.

It is not necessary to add to these two cases, which occur to me at the moment, to emphasise the fact that adverse general conditions do not always contraindicate operative interference; many more might be cited. It is a question of selection of cases here as always in surgical work. And in addition we have to study, when conditions are not as favourable as could be wished, whether they cannot be improved by general measures until an operation is admissible.

Factors Supposed to Contradict Operation.

It is worth while to consider now briefly what are some of the factors which are often thought to weigh against operative treatment of hernia. In the first place, let us take the size of the protrusion. I venture to think that there are not many herniæ too large for operation. There may be a few. But the reasons why we are well advised to refrain from operation in such cases are not always realised. It is not the actual size of the tumour that is the obstacle, for we know that many other as large or larger abdominal tumours, involving even greater interference with the viscera, may be removed safely. It is the fact that these voluminous herniæ *are not going to be taken away*—that is the difficulty. These bulky masses *have to be returned into the cavity of the abdomen*—that is the trouble. When a large bulk of the abdominal contents have escaped beyond the control of the parietal muscles the latter contract and the peritoneal cavity becomes smaller. If this condition of things has lasted long, perhaps for years, the reduction of the protrusion may be very difficult even without the presence of adhesions, and may be resented by the abdominal muscles which have accommodated themselves to the reduced capacity of the cavity. It stands to reason that if a very large hernia containing much omentum and other fat be returned into the peritoneum the pressure within is considerably increased, and sometimes with very injurious effects. Perhaps the worst of these is interference with the movements of the diaphragm. This might be of less importance to younger people, but among those past middle life with more or less rigid thoracic walls, and relying to a great extent, therefore, upon abdominal breathing, the embarrassment of the latter may be serious. This risk is accentuated if the lungs be emphysematous, or if the patient suffers from acute or chronic bronchitis, or if he be very obese and the heart be weak. I have heard and read of such cases, though I have not seen them, where the interference with respiration and cardiac action has been fatal: the patients have simply been suffocated because the movements of the diaphragm were obstructed.

A patient affected by the conditions just alluded to should be put to bed for some weeks on a strict regimen to reduce the amount of fat and fluids in the tissues, and daily attempts should be made to return and retain the hernia within the abdomen. If the mass can be reduced and cause no embarrassment to respiration, one element of danger is eliminated. The restricted diet and, before all, the denial of fluids may be reinforced by purgatives regularly to unload the bowels and further reduce the volume of the abdominal contents. There can be no doubt that many cases can be brought well within the reach of operative treatment by these means. Of course, acute bronchitis, marked albuminuria, or much sugar in the urine contraindicates immediate operation, except in cases of urgency. But even these conditions may often be ameliorated by treatment in bed with suitable remedies and free purgation, after which operation may be admissible. The very fact, so often seen, that where an operation has been unavoidable on account of strangulation, the patients have recovered in spite of the presence of these general diseases enforces this conclusion.

The next point which requires consideration is age. I do not think, apart from the conditions referred to, that age, unless it be *very* advanced, affects the question of operation necessarily. In extremely old people, of course, it is doubtful whether operation for any condition is, so to speak, "worth while." They are near the end of life in any case, and may be disposed to accept the ailment in question as their last message. Unless they are undergoing intolerable suffering they may, perhaps, be fairly left to any palliative measures suitable to their case. But we all know that many persons at 70 are younger in tissue and general vitality than others at 50. I recall a case in which some three years ago I was asked to operate on a patient on or about the anniversary of her eighty-fifth birthday for carcinoma of the transverse colon, which was causing intolerable pain. I very seriously doubted the propriety of interference at such an advanced age, but she insisted that it should be done. The result was complete relief, and she lived in comfort for 15 or 18 months longer, dying at last of old age. Such cases remind us that years alone should not be a criterion in questions of operation.

Great obesity is another condition which deters many patients from contemplating operative relief, and some surgeons from attempting it, and doubtless it is an undesirable factor. But there are many very stout patients whose general health is very vigorous and whose tissues have lost but little vitality. These may be operated on with but little extra risk. *It is the pasty, flabby, anæmic corpulence* [illegible] ted, a [illegible] in bed [illegible]

The possibility of extensive adhesions in large herniæ has also to be carefully considered. These in a lesser degree are common in such cases, but it is only when they are very extensive and involve the intestines that they become a serious obstacle to operation, mainly on account of the time lost in dealing with them. If it is only a question of adhesions between the omentum and the sac—and this is the most common condition—there is a formula I always adopt which renders them immaterial during operation. The long and tedious process of separating them is unnecessary. The omentum at the neck of the sac above where it is unadherent is simply drawn out of the abdomen, tied in whole or in part, and cut below the point of ligation. The *sac is then removed with all the adherent omentum.* This saves much time and bleeding. To tie off the root of a large omental protrusion, controlling its vessels with a few fine sutures, is a simple, quick, and effective measure. To divide old and widespread adhesions one by one on both sides is quite another thing, and if it were done the reduced omentum would carry into the abdomen many ligatures and raw surfaces likely to produce fresh adhesions within the abdomen.

In most cases of large herniæ it is not difficult to determine beforehand whether the contents are adherent to the sac or not. The duration of the existence of the rupture is some help. For it may be taken as a general rule that the older a hernia is *the more likely* are adhesions, *especially if its neck is small. If the patient has had from time to time* evidence of incarceration of the bowel—that is, more or less obstruction in it without actual strangulation—we may expect adhesions. It is believed that in these cases interference with the return of blood from the extruded bowel has led to its *engorgement and the exudation* of lymph on its surfaces. Besides this there has probably been transudation of toxins, and in some cases of bacteria, which can, we know, pass through congested though still living tissues, exciting a septic exudation and still firmer adhesions. Of course, when the rupture returns on the patient going to bed the case is simple. But in some cases of omental hernia which do not *thus return or even cannot be coaxed back* by taxis there are no adhesions. The reduction is prevented by the condensation of the omentum into a hard rounded fibrous mass which cannot pass the neck of the sac. This *is often seen* where ill-fitting and too powerful trusses have been long worn without proper reduction of the mass. Reducibility of a hernia without any interference with the movements of *the* diaphragm or other evidence of intra-abdominal pressure may be taken then as a factor favourable to operation. In some cases *a great proportion of the contents,* usually intestine, can be reduced by patience, but a certain amount remains irreducible. But as this is generally omentum it is immaterial, as it is to be removed with the sac.

The development of the muscular and fascial walls round the hernial opening has always to be considered in reference to the propriety of operation. The ring may be unusually [illegible] This was [illegible] But at [illegible] and the [illegible] rees the *objection has not its former force. Patients at the time of* life at which we are usually called upon to perform operations on large herniæ are not as a rule likely to make unusual muscular exertion for the rest of their days and can learn to spare themselves after operation.

As to the skin over and around large herniæ it is often thin and eczematous. It can, however, be rendered at least healthy and aseptic by judicious treatment during the time the patient is more or less confined to bed as recommended above. Moreover, as most of the skin will be removed with the sac between *incisions in healthy parts on either side,* the state of the skin over most of the sac is no obstacle to operation, as is indicated by the first case described above, where the integument and sac were gangrenous and very foul, and yet after their removal the healthy coverings obtained from the sides healed per primam.

When we study all the foregoing considerations I confess that the arguments against operating must be based upon very clear and special indications to influence me to refrain. Risks there are in these and all operations, but they are not very great, and the stake to be won is a very valuable one. Moreover, the risks of *not operating* are considerable, both as regards the general health and the local condition. It is a *frequent experience to see neglected herniæ in the most serious condition which might have been avoided* by an earlier operation.

The Preferable Operative Measures.

We can now consider in general terms the operative measures which can be adopted for these large herniæ.

But first and before all it is well to be clear that the preparation of the patient has the most important bearing upon the success of our procedure. Most people with herniæ, as we have seen, are past middle life and obese. As a rule, their general condition will be improved by a stay in bed for two or three weeks, not necessarily all the day or in *a recumbent position, which some cannot tolerate.* The reasons for this I have already stated. Fresh air and mental quiet are also to be secured. If the protrusion can be reduced into the abdomen every effort should be made to retain it there in order that all the viscera shall become accustomed to its presence once more, and especially the diaphragm. Pulmonary, cardiac and renal troubles may of course be so marked as to contraindicate any operation, but in their milder forms may be improved by the rest in bed combined with dieting and suitable drugs. Some or all have often been present in cases of strangulated herniæ, and have not frustrated the operation or prevented recovery, as we know.

The rest in bed will also usually enable us to secure the *highest possible standard of cleanliness of the skin all over the field of operation. This is not always an easy matter,* for large herniæ are very prone to become eczematous under the pendulous parts, especially if umbilical or ventral, and this intertrigo is apt to become very foul. Large herniæ about the groin, too, require great care in this respect. All will require daily washing with the hottest water that can be borne and often astringent antiseptic lotions for a long time before we can trust them to be practically aseptic. No operation should be done that can be avoided until we are sure of our ground here. Finally the night and day before operation there is no better antiseptic application than a 2½ per cent. solution of iodine in ethylene dichloride painted *freely over the whole field of operation.*

The question of the proper anæsthetic to be used will be variously answered for different cases. I do not think any hard-and-fast rule should be followed. A local anæsthetic is, of course, *the safest, and I use it frequently.* But for very large herniæ it is difficult to secure perfect analgesia over the extensive area involved, and it does not produce that general muscular relaxation which *is so desirable* when we have to reduce very bulky contents.

Inhalation of ether has much to recommend it if combined with a preliminary injection of atropine, especially if the operation be protracted. But it is apt to produce coughing and straining, which are very embarrassing when the hernial contents have to be replaced, and respiratory troubles are likely to follow its prolonged use.

Venous infusion of ether is well suited for these cases, giving good relaxation and perfect quiet when well administered. It keeps up the patient's strength, too, during a long operation by virtue of the amount of saline solution carrying the ether. There is less objection here to its undoubted *effect of encouraging bleeding, inasmuch as* the tissues to be divided in a hernia operation are less vascular than in most others.

The objections to chloroform in good hands are, in my opinion, not great as a rule, but when pushed as far as absolute relaxation, so desirable in these cases, its dangers are well known.

Spinal analgesia well carried out gives ideal conditions for the operator, and though it has dangers, the full extent of which are not yet known, it is superior to the foregoing in many ways. I have used it now in some hundreds of cases of hernia operations without a fatality, and it has certainly facilitated the accurate performance of them to a degree that no other anæsthetic could do. The absence of rigidity of the muscles and of all respiratory excitement during and after operation renders the procedure very easy. Then the patient can take nourishment within a few hours, and this is of great importance, especially in elderly people. But, as I said before, each case must be considered on its merits.

It is assumed that in all these cases purgatives have been freely used for reasons given. These should, however, be stopped at least 48 hours before operation, to give rest to the bowels, which are otherwise likely to be distended with gas. The night before operation an enema will clear out the rectum and relieve flatulence if some turpentine be added.

As to the various methods of operation to be performed for these large herniæ, I have described them so recently in the "System of Operative Surgery," edited by Mr. F. F. Burghard,[2] that it is not necessary to go into detail about them, but some general remarks on them will not be out of place.

Speaking generally, I have in almost every case found Bassini's operation carried out with every attention to detail to be quite adequate for all inguinal herniæ great and small, and I consider it the best method when done with care. In some cases where the tissues are very slack the modification of overlapping the edges of the rings described by Halsted[3] will be found to give a thicker scar than that formed by merely drawing the edges together. The large sac need not be dissected formally out of the scrotum. At its neck, of course, it must be separated and for some little distance. To do more is to risk considerable oozing into the areolar tissue of the scrotum and a troublesome hæmatoma. An exception to leaving the sac intact in the scrotum is when the contents are almost universally adherent. Then it should be removed with the attached omentum. When this is separated at the neck and well drawn down it is tied off and cut across, the lower part of the sac when adherent to the omentum being taken away with it, or if non-adherent left open, as much of it being removed as was separated below the neck. It must not be forgotten that when the veins of the cord are pressed upon by the reduced rings an engorgement of the veins of the scrotum follows which favours oozing, so that all small and large bleeding points should be attended to before the wound is closed. If, in spite of this, there is still a tendency to ooze, a drain should be introduced for 24 hours, as a hæmatoma in this region may be troublesome. After 24 hours the drain will probably do no good, and may even form a track for the infection of the part from without. The possibility of septic matter lurking in the folds of the scrotal skin and its hair, sebaceous and sweat follicles, must always be borne in mind. Unless great care has previously been taken in the daily preparation of the scrotum to encourage these glands to act freely and carry any hidden bacteria to the surface, the danger of infection during or after operation is considerable. Frequent washings with soft soap and water as hot as can be tolerated are called for, followed before operation by the iodine solution. But the latter must be used with caution, as I have seen it produce eczema in some cases. In many cases the washings, supplemented just before operating by the free use of spirit, will be quite sufficient. A moist eczematous condition here may be very troublesome.

As to the use of silver filigrees inserted deeply in inguinal herniæ to add strength to the abdominal wall, I venture to think that in the large majority of cases they are unnecessary. A strong enough barrier to the redescent of the hernia can be made without them by suturing. But I have used them, I think with advantage, in some few cases where the structures were very thin and atrophied; at all events, they appear to be less required and more difficult to arrange here than in the large ventral and umbilical herniæ. In the latter they seem to me to be of the greatest value, not only because they give a certain amount of support for a time, but because I believe their presence in the tissues provokes an exudation of lymph without sepsis, which organises into particularly firm fibrous tissue. I have seen to-day a man the greater part of whose left rectus muscle I had to take away three years ago because it was involved in a carcinoma of the transverse colon which had fungated through it. Here there was little or nothing to replace the muscle, and I covered the opening with a silver filigree and drew the skin over it. And now, though the scar is very thin, thin enough to be moved by the intestines underneath it, there is no hernia, although the man plays golf and is a performer on a wind instrument. Both these strains are well borne, and would infallibly have caused a hernia if the support had been as weak as it certainly appears thin. The use of these filigrees is only required, as a rule, in very obese people with one or other form of ventral hernia the rings of which are loose and so thin that there is but little material to work upon for making a firm barrier to redescent of the rupture. Here the filigree may be inserted either directly upon the closed peritoneum and transversalis fascia or within the sheaths of the recti muscles after they have been opened vertically on either side; the edges of the sheaths being united over it and the skin over this. Many ingenious plastic operations have been devised to meet the needs of these extreme cases, and some of them I have practised. But none appear so rational and feasible as the support by filigrees. Several objections have been raised to their use. So far as I can see the most justifiable is that the wire may break in course of time, and the broken ends cause irritation. This has happened, but is only of moment if too thick a wire has been employed. When the wire is very fine no harm can arise; the network remains a support broken or unbroken, and from what I have seen the fibrous tissue formed about it is particularly firm and strong.

Another objection is that if suppuration occur the wires must be taken out, and this is a matter of great difficulty and leads to weakening of the scar. But this need not be done. I have planted filigrees in wounds actually suppurating, and far from their keeping up the inflammation, they have appeared to control it, probably, as has been pointed out, because of the silver salts produced in the tissues by chemical action on the wires. The antiseptic action of the silver salts is well known. Be this as it may, I have seen such suppurating and granulating wounds heal over the wires in a way which suggested that they were quite harmless if not beneficial, as in the case quoted just now which I have seen to-day. Once recently, in operating through an old abdominal scar into which some surgeon whose name I do not know had inserted a wire network, I came upon many broken pieces of silver wire and removed them. But these were far and away too thick. They were somewhere about a millimetre in gauge instead of being like medium-sized sewing thread. The fact of the matter is that some scores of my cases have been going about for years with these filigrees in their scars, and from what I have seen of them I feel sure to their benefit. Indeed, in some cases of very large herniæ with wide thin rings it is hard to imagine any other mode of giving support.

In this brief sketch of a very large subject I have tried to give some general considerations which have guided myself in dealing with a most troublesome class of cases. I have, in the first place, had no mortality among them, which shows that it is possible to avert the dangers which have undoubtedly to be faced. And the results *quâ* non-recurrence have been very encouraging. In some very obese patients, with more or less pendulous abdomens, I advise them to wear a well-fitting broad belt or bandage after operation for ventral hernia. This will help to bear some of the weight of the parts. But in most cases this is not necessary. These patients should also be advised to avoid everything which contributes to their corpulence and to take regular moderate exercise. For every reason the amount of fat in their tissues should be reduced.

Before closing, may I draw attention to a snare which sometimes awaits the inexperienced in operating in inguinal herniæ with large rings? This is the presence of part of the bladder in the sac. I have seen many such cases (two operated on in private since this lecture was sketched out) and recognised the condition in time to avoid injury to the viscus in every case. But it is a condition which might easily lead to disaster, and has done so, as we know from several published cases.

Harley street, W.

THREE CASES OF POLYCYTHÆMIA.

BY T. K. MONRO, M.A., M.D. GLASG.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY, AND PROFESSOR OF MEDICINE IN ST. MUNGO'S COLLEGE

With Report on the Necropsy in One Case

BY JOHN H. TEACHER, M.A., M.D. GLASG.,
PATHOLOGIST TO THE GLASGOW ROYAL INFIRMARY AND ST. MUNGO (NOTMAN) PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF GLASGOW.

THE subject of polycythæmia has been discussed so recently, so elaborately, and with such lucidity by Dr. Parkes Weber[1] that only a brief statement is required by way of introduction to the following records of cases. It may be recalled, however, that polycythæmia (polycythæmia rubra, polyglobulism) means an excess of red corpuscles (erythrocytes) in the blood. This excess may be relative or absolute.

I. Relative polycythæmia is due to concentration of the blood, as in cases of severe [illegible]

II. Absolute or true pol[illegible] vera) is due to excessive [illegible] marrow. In this condition the hæmoglobin is increased as well as the erythrocytes, but the colour index is usually below 1. The total volume of the blood is often, if not always, increased (polyæmia, plethora vera). The viscosity of the blood is increased. The coagulability varies independently of the richness in erythrocytes and hæmoglobin. True polycythæmia may be either symptomatic or primary.

1. Symptomatic or secondary polycythæmia is an erythrocytosis, analogous to a leucocytosis. It is met with in cases of chronic cyanosis associated with heart or lung disease, and *it is also found in man and other animals living at high* altitudes. This erythrocytosis is compensatory in its nature, and is attributable to stimulation of the bone marrow by the deficiency of oxygen.

2. Primary polycythæmia or erythræmia is analogous to leukæmia, *there being no obvious reason why the bone* marrow should show the excessive erythroblastic activity. It is known by a variety of names, including "Vaquez's disease," "Osler's disease," "splenomegalic polycythæmia," "myelopathic polycythæmia," "polycythæmia with chronic cyanosis," and "erythrocytosis megalosplenica." These titles, however, are not all suitable, since cyanosis is absent in some cases, while in other cases there is little or no splenic enlargement. Whether the syndrome represents a single morbid entity, a disease *sui generis*, may be more definitely ascertained when a greater wealth of pathological and clinical material has accumulated, and the degree of affinity between the different types can be more precisely determined.

The symptoms in the initial stage may be of a vague as well as varied character, and it is probable that the disorder of the blood may exist for a considerable time before it causes any grave or manifest disturbance of the general health. It is further probable that the disease would be found to be more common than is generally recognised if an examination of the blood were a more constant routine of clinical work. The following cases illustrate different aspects of the affection.

CASE 1. *Polycythæmia; cyanosis; ? splenomegaly.*—Captain X. Y., aged 47, formerly a master mariner, but now employed on shore, was [illegible] Oct. 2nd, 1911.

[illegible] k as December, 1906, the [illegible] ndition of the urine, but no [illegible] He gave a history of con- [illegible] wer abdomen, but nothing [illegible] t was afterwards discovered that he had a stricture, and he was sent to a surgeon for treatment. [illegible]

[illegible] attack.

[illegible] of the teeth were bad. [illegible] stomach, which were [illegible] week he would have a [illegible] up, followed by a little [illegible] It was seldom that he [illegible] that he had lost about [illegible] was no marked loss of strength.

Examination showed that, with the exception of lack of purity of the second aortic sound, the physical signs connected with the heart were [illegible] *disease of the aortic arch.* The [illegible] ps thickened. The lungs were [illegible] he spleen or superficial lymph [illegible] appearance.

The patient had never suffered from malaria, dysentery, or yellow fever. He used to smoke about four ounces of tobacco weekly, in [illegible] nded to diminish the consumption [illegible] ondition of the fauces improved. [illegible] of Gregory's powder was recom- [illegible] ll dose of mercury was to be taken twice a week, and he was to have a tonic containing nux vomica. Red meat was to be taken only once a day, and he was to guard against constipation.

April 29th, 1912.—The patient called again to see me He had not been at sea since his last visit, but was on full duty ashore. The following is an account of his condition.

He says he has lost little weight, if any, since his last visit, and he feels much better in every way than he was two years ago. His stomach and bowels are now in very fair condition, though the tongue [illegible] thick fur. The appearance of the face [illegible] or purple colour over the nose and [illegible] ins; but over the rest of the face, [illegible] olour is red without any admixture [illegible] The appearance is the more striking in view of the complete absence of any evidence of respiratory embarrassment. He says that when he walks smartly the face is particularly apt to become blue, but he has no shortness of breath, [illegible]

[illegible] The abnormal redness is seen on the surface of [illegible] In any part [illegible] rief duration [illegible] red and the retinal veins are large and very dark in colour, but otherwise the fundi are normal.

[illegible] at work during the whole of the year 1911, but did not resume duty after last New Year holidays. He had lost much flesh and strength since the New Year.

It was found [illegible] the spine in th[illegible] stooping, but r[illegible] patient walked [illegible] an indoor patient on May 21st, 1912, and he remained in the wards till June 21st.

---

[1] Quarterly Journal of Medicine, vol. ii., No. 5, October, 1908.

Previous health.—He had pneumonia on the right side about 12 years ago, and he fancied he had never been quite so strong since. He had catarrh of the stomach eight years ago, and was very ill for 14 weeks. He had always been nervous and given to worrying. No information was obtained as to the family history.

Condition while in the wards.—Examination of the heart, lungs, liver, spleen, superficial lymph glands, testes, rectum, urine, and fundi revealed normal conditions. The appetite was fair. There was no vomiting, and the bowels were regular. The temperature was subnormal all through, and the weight remained constant. There was pain on pressure over the internal semilunar cartilage of the left knee-joint.

Examination of the blood showed that it was abnormally rich in red corpuscles, and at times in hæmoglobin also. The white cells might be normal, or deficient, or excessive in number. The colour index was usually below normal.

Date.	Red corpuscles per c.mm.	White corpuscles per c.mm.	Hb. per cent.	Colour Index.
May 25th, 1912	6,700,000	3,125	100	0·75
,, 30th ,,	5,834,000	12,500	120	1·0
June 14th ,,	7,133,000	8,432	110	0·77
,, 20th ,,	6,500,000	8,750	110	0·85

Differential count of white cells.—Polymorphs, 56·12; lymphocytes, 26·02; mononuclears, 17·34; and basophiles, 0·51.

Blood pressure (Oliver's manometer).—May 31st, 1912: systolic, 120 mm. Hg; maximum pulsation, 100 mm. Hg; minimum pulsation, 80 mm. Hg. June 20th, 1912: systolic, 135 mm. Hg; maximum pulsation, 105 mm. Hg; minimum pulsation, 70 mm. Hg.

The blood was examined bacteriologically by Mr. J. Archibald Campbell, and was found sterile after 72 hours' incubation.

On June 20th it was noted that there had recently been distinct hyperæmia observed on the surface of the body, not only on the face, but also on the trunk, forearms, and hands.

Condition in September, 1912.—The patient called at the wards on Sept. 9th and 10th. He still complained of general weakness, and said that he became short of breath on going upstairs or walking any distance. His weight had fallen from 8 st. 7 lb. on June 15th, to 8 st. 3 lb. on Sept. 10th. The pinkish colour of the forehead was still recognisable, [illegible] merly.

There was [illegible] of the heart, and the heart sounds were n[illegible] dilatation of the aortic arch. The radials w[illegible] eir tension did not appear to exceed the normal. The lungs were healthy. A scar was found in front of the right sternomastoid muscle, where an operation had been performed in boyhood, but elsewhere the superficial lymph glands were normal. There was no enlargement of the liver, and no certain enlargement of the spleen. The optic discs were healthy.

On Sept. 9th the red corpuscles numbered 7,800,000 and the white cells 3000 per c.mm. The hæmoglobin was 110 per cent., and the colour index 0·7.

CASE 3. *Polycythæmia; splenomegaly; excessive arterial pressure; arteriosclerosis, with gangrene of the toes, fibrosis of the kidneys, and retinal changes; no cyanosis; fatal issue and necropsy.*—The patient, aged 45, Jewish, a tailor's presser, was admitted to the Royal Infirmary under the care of Mr. H. Rutherfurd, on August 11th, 1911. The man's complaint was of pain in the toes of both feet, which had troubled him for four months, and had been specially severe during the last few weeks. It was found that gangrene was threatening the toes, the arteries were sclerosed, the spleen was enlarged, and the urine contained albumin. As the case was recognised to be medical rather than surgical he was transferred to my wards on August 18th.

According to the history given, pain set in gradually in both great toes about the beginning of May, 1911. The condition of the right great toe became steadily worse, and a month or two before admission its colour became dark. There were tingling and pricking as well as pain, and sleep was much disturbed. The left great toe became easier. The patient continued at his work until two or three weeks before admission.

Past history.—The patient was under the care of Dr. Ebenezer Duncan in the Victoria Infirmary from April 9th to May 27th, 1905, and through the courtesy of Dr. Duncan and the superintendent, Dr. D. O. Macgregor, I have been able to ascertain some facts about his condition at that time. His age was stated to be 40, and he was admitted as an urgent case of hæmatemesis. It was reported that his stomach had troubled him for some years, an[illegible] been gradually becoming blind during the two [illegible] his admission (see, however, later in this [illegible] lungs were found to be healthy, and no tumour or dilatation of the stomach could be detected. The spleen was much enlarged, its lower border being at the level of the umbilicus and its anterior border almost at the middle line. The red corpuscles numbered 2,900,000 and the white cells 22,800 per c.mm. A differential count of the white cells showed the polymorphs to be 73·9, the lymphocytes 20·6, the eosinophiles 2·4, and the large mononuclears 3·1 per cent. The right eye was found to be blind, with atrophy of the disc, and with disturbance of [illegible] The patient got on very well so far [illegible] were concerned, but Dr. Macgregor [illegible] rived from X ray treatment of the enlarged spleen.

The continuation of the past history, which was obtained after the patient's admission to the Royal Infirmary, shows that he had left-sided pleurisy four or five years ago. From about that time onwards he suffered from frequent headaches and from constipation. He continued liable as before to suffer at times from pain in the stomach after taking food. After some years he got into the way of drinking more fluid and passing more urine than before, and he found that he was very easily fatigued. After the trouble with the toes began he lost flesh. He claimed to be a very [illegible] that he spent scarcely 10*s.* a year on liquor [illegible] ever had any venereal disease, though he adm[illegible] nfection. In May, 1912, while he was resident in the wards, his blood was examined by Wassermann's test, and this was found to give a negative result.

He had not suffered from shortness of breath, palpitation, faintness, giddiness, or tinnitus. It may be added here that at no time was cyanosis a feature of his case.

Family history.—His parents both died in old age. The family consisted of five members, all of whom survived. The other four were healthy. The patient himself was married and had four children, all of whom were healthy.

Condition on admission (August, 1911).—The right great toe was painful, swollen, cold, extremely tender, and discoloured, being partly red and partly dark blue. The left great toe was slightly discoloured and tender. The pulse was regular and of high tension, and the arterial walls were thickened. The apex beat of the heart corresponded to the nipple line. There was no murmur. The lungs were healthy. The liver did not appear to be enlarged. The spleen was considerably enlarged, so that its lower border could be felt at a level half an inch above the umbilicus. The urine contained a trace of albumin, but no sugar. There was no œdema of the legs. The reflexes were normal.

Other facts noted in the course of his residence are as follows:

Eyes.—The patient stated that he became suddenly blind in his right eye 17 years ago, when he was in excellent general health. There was pain in the eye for some weeks before the blindness set in. Examination showed that the disc was atrophied and that the arteries were greatly narrowed. In the macular region there were white spots and streaks of degeneration, and there were in addition numerous collections of black or brown pigment. This eye was the seat of severe pain for some weeks before he became blind. On account of the blindness in the right eye no mydriatic was used at this period for the left eye, and the macular region was not properly observed. It was noted, however, that the disc was hyperæmic.

Blood.—In the course of his resid[illegible] varied from 5,800,000 to 6,400,000, and [illegible] to 20,400 per c.mm. The hæmoglobi[illegible] The colour index, therefore, was below [illegible] the white cells on Nov. 29th gave the [illegible] eosinophiles, and basophiles, together, [illegible] 21·23 per cent.; transitionals, 1·77 per cent.; myeloblasts, 0·4 per cent.; and mononuclears, 0·9 per cent.

The systolic blood pressure was from 180 to 210 mm. Hg. There was some enlargement of lymph glands in both axillæ and in the left groin. The distal portion of the right great toe dropped off on Dec. 3rd.

Dismissal.—The patient was dismissed on Dec. 15th "improved." He had been treated principally by opiates, which were needed to relieve his pain, but from Oct. 9th to Nov. 25th he got potassium iodide in doses of 10 grains thrice daily.

Readmission.—He was readmitted on March 9th, 1912, on account of pain and discoloration in the toes of both feet.

Note of May 3rd, 1912.[2]—Since his readmission on March 9th the patient has suffered a good deal of pain, either in his feet or in his head. Several of the toes of both feet are the seat of actual or threatened gangrene, and the pain associated with this condition has required opiates for its relief. For a time he suffered severely from headaches, but the regular administration of trinitrin, and the use of phenacetin and citrate of caffeine, were followed by excellent results. The temperature has been almost uniformly subnormal. The pulse-rate has been slightly accelerated. General cyanosis is not a feature of the case. The splenomegaly continues. There i[illegible] ment of the liver. The enlargement of the [illegible] there is no murmur. The lungs appear to [illegible] blood pressure was 210 mm. Hg on readmission, but fell during the administration of triniti[illegible]

The condition of the [illegible] is present residence. The red corpusc[illegible] on readmission to 4,000,000 per c.mm. [illegible] fell from 120 to barely 100 per cent., and [illegible] 125 per c.mm. A differential count of the white cells made yesterday showed the polymorphs to be 81 per cent., the lymphocytes 13, and the large mononuclears 5 per cent. The blood readily penetrated the papers used in connexion with two hæmoglobin scales. Dr. H. H. Borland found this morning that the coagulation period of the blood was 6 minutes 5 seconds.

The urine has recently had a specific gravity varying from 1008 to 1015. Albuminuria is distinct, but there is no sugar. On a recent date, by aid of the centrifuge, a considerable number of granular casts were detected.

[illegible] after dilatation of the pupils, [illegible] imilar to that described in the [illegible] ative changes in the macular [illegible] In the left eye there is neuro-[illegible] isable except in a dim way at the lower inner part. The evidence of the swelling of the papilla is most distinct at the upper and upper inner parts. Linear hæmorrhages are present. In the macular region there are early degenerative changes of albuminuric type. Low down in the fundus there is a circular, reddish-brown area, which suggests a hæmorrhage clearing away.

Last phase of the illness.—In the latter part of his life the patient suffered greatly from pains in the legs, and required large doses of opiates. On May 9th an examination of the blood showed that the red corpuscles numbered 4,200,000 and the white cells 10,000 per c.mm. A differential count of the white cells made on May 12th showed that the [illegible] to 73·4, the lymphocytes to 18·0, the mono-[illegible] philes to 1·8, and the mast cells to 0·5 per cent. [illegible] rly in June it was noted that gangrene was [illegible] the feet, and several of the toes were separat-[illegible] iver was found to extend two inches below the costal margin. Blood taken on the same day by Mr. Campbell for [illegible] tion proved to be sterile after 72 hours' incuba-[illegible] on June 21st.

[illegible] st important remedy was opium or one of its derivatives, which was rendered necessary during a great part of the patient's residence by the severity of the pain. From Oct. 9th to Nov. 25th, 1911, he got potassium iodide, in doses of 10 grains, thrice daily. In March, 1912, he got a tonic containing sodium bicarbonate, [illegible] On March 29th trinitrin was begun, and this [illegible] On May 15th he began to get the [illegible] for excessive arterial pressure, and [illegible] consisting of potassium nitrate and potassium bicarbonate, of each 10 grains, with sodium nitrite 1 grain, to be taken each morning in hot or aperient water. An attempt was made in the end of May and beginning of June to apply X rays over the spleen but this had to be desisted from on account of the feebleness of the general condition

---

[2] The patient was shown on this date to the Glasgow Medico-Chirurgical Society.

The following table shows the blood counts and the hæmoglobin at different dates —

Date	Red corpuscles per c mm	White corpuscles per c mm	Hb per cent

* On readmission

It has been known for some time that there is a special group of cases of erythræmia which is characterised by excessive blood pressure, and the recognition of the fact is due largely to the work of Geisbock Indeed, the late Professor Senator, in his essay on "Polyzythämie und Plethora," published in 1911, divides cases of primary (idiopathic) polycythæmia into the two classes (1) polycythæmia rubra (erythrocytosis) megalosplenica, or Vaquez s disease, and (2) polycythæmia hypertonica (Geisbock) He points out that Geisbock's disease is distinguished from Vaquez s, not only by the remarkably high blood pressure, but also, as a rule, by enlargement of the left heart and by the absence of splenomegaly He considers that the high pressure is due partly, but by no means exclusively, to the viscosity of the blood He does not believe that the two forms can be sharply separated from one another, but thinks it very probable that there are transitional forms which connect them In the cases described in this paper different intermediate types are represented It is, of course, possible that the polycythæmia and florid colour of the skin in the second case may in time come to be associated with enlargement of the spleen In the third case there are the

changes in the blood vessels, heart, kidneys, retinæ and limbs which are associated with, and to a large extent the result of, the high pressure, in themselves remarkable phenomena but they are of interest in view of the Jewish descent of the patient, and the special tendency shown by that race to suffer from obliterative arteritis at an age too early for senile gangrene of the usual kind

It has been suggested that polycythæmia with or without splenomegaly, may arise, even though there is no disease of the heart or lungs, through a local obstruction to the circulation, such as is present in extreme passive congestion of the portal system The third case described might actually be cited as lending support to this hypothesis But in opposition to this theory, it is to be noted in the first place that the typical spleen met with in chronic passive congestion from heart disease is not a large one, in the second place that splenomegaly and polycythæmia may be present, as in the third case, without cyanosis, and in the third place, that the disturbance in the portal vessels may, like that in the vessels of the limbs, be a late phase, and not a primary factor, in the evolution of the disease Unless cyanosis is present the theory referred to is scarcely intelligible

Report of Necropsy in Case 3 and Commentary by Professor TEACHER

The post mortem examination in Case 3 was made on June 22nd 1912 The body was extremely emaciated and livid and there was

there was a globular thrombus of the size of a marble and the extreme apex of the heart to about *the size of a penny* was *found to be* in a state of recent infarction The coronary arteries showed extreme nodular thickening amounting to almost complete obstruction in the case of the main anterior branch There were large agonal thrombi in all the cavities of the heart

The *lungs* showed extreme venous congestion and a number of early infarctions caused by masses of red thrombus

The first

patches

were very

each abo

thoracic

intercostal arteries were absent In the abdominal aorta there was a very large atheromatous patch with great thickening of the tunica intima and a somewhat contracted appearance but white in colour being free from fatty degeneration or calcification The cœliac axis and superior mesenteric arteries appeared to have arisen by a common trunk in the normal position of the latter This was about the centre of the atheromatous patch, and the orifices of the renal arteries lay just within its lower margin The orifice of the mesenteric vessel was completely occluded while both the renal arteries were narrowed to an extreme degree The lower part of the aorta and the iliac and femoral arteries also showed atheromatous patches The aorta and arterial trunks appeared to be generally thicker and more rigid than normal

veins were abnormally large and prominent The stomach and intestines showed general pronounced venous congestion and the mesenteric veins were noticeably enlarged close to the attachment of the bowel

The *liver* was somewhat enlarged firm and chronically congested, being of fairly advanced nutmeg type There were a few fibrous

representing the thrombous

The *spleen* was considerab

estimated to weigh at most

channeled

of the

lasia of

firmed

The *brain* showed slight atrophy of the convolutions and œdema of the meninges The large vessels at the base were comparatively healthy in appearance

Further dissection confirmed the appearance of old thrombosis of the portal vessel back to its origin at the junction of the splenic with the superior mesenteric vein and of the latter into the mesentery Everywhere the vessel and its radicles were channeled and masses of new vessels had been developed round about them (The stellate appearance in section could be traced well out in the splenic and main mesenteric veins)

The arterial supply of the parts dependent upon the cœliac axis and superior mesenteric artery had been maintained, except in the case of the spleen, by means of a very large anastomosing connexion with the inferior mesenteric artery, assisted probably by smaller communications from the lower intercostals and two vessels of about the size of crow quills which arose a short distance above the *inferior mesenteric* artery and passed towards the ascending colon The main vessel concerned was the left colic branch of the inferior mesenteric which was of about the size of an ordinary superior mesenteric artery and ran a very tortuous course along the descending and transverse colon until it anastomosed with the superior mesenteric trunk through its middle colic branch. From the right side a vessel of about the size of a large crow quill ran along the ascending colon and joined this anastomosis. It was supplied probably by the two vessels mentioned above. Doubtless the obstruction at the orifice of the superior mesenteric artery had been of gradual development, at least up to a point, so that time had been allowed for the development of the anastomosing system, and thus all its branches and those of the cœliac axis had continued to receive a sufficient supply of blood with the exception of the splenic artery close to the spleen.

Whether this last was obstructed by embolism or, as is more probable, by thrombosis, it is impossible to say; but there is no evidence of embolism having occurred elsewhere, and the splenic artery was tortuous and sclerotic. It appears, therefore, more probable that the cause of the obstruction was a thrombosis occurring close to the spleen. In 1911 I reported, along with Dr. R. S. Taylor,[3] a case in which advanced disease of the splenic artery led to thrombosis and infarction of the greater part of the spleen. From this infarction, apparently, thrombosis had started in the splenic veins and spread until it involved the portal vein, and the patient died with acute symptoms of obscure character which were only explained post mortem. It is probable that something similar had occurred in the present case, though there is no record of any illness manifestly corresponding to such an occurrence.

In conclusion, it appears most probable that the patient was a chronic sufferer from splenomegaly of obscure nature and arteriosclerosis. The gradual occlusion of the superior mesenteric artery favoured the occurrence of thrombosis in the splenic artery, and the resulting infarction of the spleen led to portal thrombosis. The whole abdominal condition, then, might be described as a freak of arteriosclerosis producing a localised venous congestion, which in a number of other cases has been the only explanation which could be offered of polycythæmia.

A SERIES OF 236 CASES OF TOTAL ENUCLEATION OF THE PROSTATE PERFORMED DURING THE TWO YEARS 1911-12.

By P. J. FREYER, M.A., M.D., M.Ch. R.U.I.,

LIEUTENANT-COLONEL, I.M.S. (R.); CONSULTING SURGEON, QUEEN ALEXANDRA'S MILITARY HOSPITAL; SURGEON, ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES.

In a paper published by me in The Lancet of April 8th, 1911, I reviewed the results of 800 cases of my operation of total enucleation of the prostate for radical cure of enlargement of that organ performed by me down to the end of 1910. During the two years that have since elapsed I have performed a further series of 236 cases of this operation. In the present paper I propose placing the results before the profession, giving in detail some cases mainly illustrative of the difficulties and complications met with in the operation, and winding up with a brief review of the 1036 instances of the operation completed by me at the end of 1912.

Case 803.—On Dec. 12th, 1910, I saw, in consultation with Dr. P. Enrigue Caballero, *attaché à la Légation du Pérou*, a Peruvian patient, aged [illegible] suffered from hæmaturia and again five [illegible] consulted a medical man, who said he was [illegible] the bladder. I introduced a catheter and [illegible] residual urine, which was mixed with blood [illegible] ed in quite easily. On examination per rectum I was surprised to find that the prostate was enormously enlarged, rounded, smooth, soft, and movable. The patient being very stout, bimanual examination gave no additional information.

On Jan. 9th, 1911, I enucleated the prostate entire, Dr. Caballero being present. More than one-third of the mass, which was pear-shaped, lay in the bladder. Though very massive, weighing 7½ oz., the enucleation was quite easily accomplished, the operation lasting only three minutes. Recovery was uneventful, some urine passing per urethram on Jan. 25th, and the suprapubic wound being dry on Feb. 3rd. On Feb. 16th the patient left the surgical home in good health, able to pass and retain his urine, which was normal, as well as he ever did. Dr. Caballero informs me that he hears from Lima that the patient is quite well and that "the operation was a great success."

The remarkable feature of this case is that, though the prostate had attained to an enormous size, the enlargement was not accompanied by any of the usual symptoms resulting from obstruction with the exception of hæmaturia. The ease and rapidity with which a large prostate of this size was removed from a very stout patient are noticeable.

Case 809.—On Jan. 27th, 1911, I saw, in consultation with Dr. Horace Duncan, a Church dignitary in his ninetieth year, who had suffered from the usual prostatic symptoms for 16 years, during the early years of which he had repeated attacks of retention of urine, relieved by the catheter. He had been entirely dependent on the catheter since 1905, and had had repeated attacks of cystitis and rigors with high fever. He also had had repeated attacks of orchitis. The bladder had been washed out daily for months; and he had had vaccine injections by an expert for three months, without any diminution in the symptoms. Dr. Duncan had for many years advised removal of the prostate, but the patient was dissuaded from this course by the surgeon consulted. When I saw the patient he was in such utter pain and misery that he begged for operation at any risk. I passed a catheter, which was introduced 16 inches before any urine flowed; six ounces of urine containing pus and blood came away. The prostate was of enormous size, filling the rectum and bladder, and felt bimanually to be of the size of an infant's head; it was quite soft and movable. The patient's general health was fair for his age, but the pulse was intermittent and irregular with high tension.

On Feb. 1st, Dr. Duncan assisting and Mr. Carter Braine being the anæsthetist, I enucleated the prostate entire into the bladder, but had then to break it in several pieces to deliver it through the suprapubic wound, which I had designedly made of limited extent. The weight of the prostate was 12¾ oz. The operation was well borne; in fact, the patient scarcely seemed to feel it. No un[illegible] intervened, the patient being bright and cheerful [illegible] bed and reading from the second day after the operation. S[illegible] was passed naturally on Feb. 22nd and 27th, and afterwards the whole of the urine was passed per urethram. On March 10th the patient left the surgical home in fair health, retaining and passing his urine as well as he ever did.

Case 858.—The patient, aged 68, was admitted to St. Peter's Hospital on June 11th, 1911, with an over-distended bladder from retention due to prostatic enlargement. Seven years previously he had had retention of urine, and the catheter had been employed for about a month; he went on fairly well without the catheter for six years after this. A year ago he had had hæmaturia for three or four days, and about monthly since then. Latterly the urine dribbled away from him, the overflow being due to over-distension of the bladder. He had had complete retention a week ago, and the catheter had been used daily since then. The pulse was rapid and intermittent, and he suffered from chronic emphysema and bronchitis. A small catheter was introduced and tied in, and the bladder was slowly drained. The urine was alkaline and contained much pus and albumin.

On June 14th I drained the [illegible] to relieve the backward pressure on the kidn[illegible] before enucleating the prostate. [illegible] improved, and a fortnight after [illegible] prostate, which weighed 3 oz. [illegible] occasions. A rapid recovery en[illegible] condition described, and the [illegible] normally on and after July 19th. On the 27th he died suddenly from heart failure. He had been walking about for several days, and was to have gone home the day after the fatal occurrence.

This case illustrates some of the conditions under which it is advisable to operate in two stages, draining the bladder in the first instance to relieve the backward pressure on the kidneys and so enable them to regain their functions, as also to cure the cystitis, before enucleating the prostate. Though the death of the patient was due to heart disease, and occurred when he was quite convalescent from the operation, it must for statistical purposes be accepted in connexion therewith, though apparently quite independent thereof.

Case 903.—On Nov. 14th, 1911, I saw, in consultation with Mr. J. J. Day, of Sandwich, a patient, aged 63, who had suffered from prostatic symptoms for five years and had been entirely dependent upon the catheter for a fortnight. There was much blood as well as some pus in the urine, and the catheter passed in some 13 or 14 inches before the urine flowed. The patient was extremely stout. On Nov. 16th I removed the prostate, weighing 3 oz., Mr. Day and Mr. Sydney B. Hulke being present. The operation was extremely difficult, chiefly owing to the stoutness of the patient, the abdominal fat being some 5 inches deep before the recti muscles were reached. The bladder wall was very thickened and its cavity contracted. These conditions necessitated extreme efforts to reach the distal aspects of the prostate by the enucleating finger in the bladder. The operation was well borne and the wound healed rapidly without any sloughing of the abdominal fat. On Dec. 8th some urine was passed per urethram, and the suprapubic wound was dry on and after the 18th. On Jan. 17th, 1912, the patient went home in excellent health, passing and retaining his urine normally. On March 5th, 1913, he wrote: "I am keeping wonderfully well, and have not had the slightest urinary trouble since I left No. 11" [the surgical home].

This case is recorded to illustrate the fact that enucleation of the prostate is feasible, though difficult, in extremely obese patients.

Case 921.—This patient, aged 79, was admitted to St. Peter's Hospital on Jan. 9th, 1912, suffering from prostatic symptoms which had commenced some 26 years ago. He was in great distress, having to pass the catheter every hour almost by day and night. He was unable to pass any urine naturally, the catheter having been employed for 23 years. The introduction of the instrument was frequently attended by hæmorrhage, and the urine contained much pus and mucus; specific gravity, 1018.

On Jan. 18th I enucleated the prostate, which weighed 3½ oz., and presented a large median outgrowth in the bladder. A small phosphatic stone was removed from the bladder at the same time. On Feb. 12th the patient was discharged, able to retain and pass his urine naturally without the aid of a catheter as well as he ever did. On March 10th, 1913, he wrote to me: "I am glad to say I am a new man since you did the operation on me, before which I was using the catheter for

[illegible] unable to follow [illegible] up ladders, &c., [illegible] This patient [illegible] to see him, in his [illegible] man of 55. His [illegible]

The complete recovery of the bladder functions in this case after 23 years of "catheter life" is remarkable. I have previously recorded[1] a case in which on Nov. 17th, 1902, I removed the prostate weighing 6¾ oz. from a patient aged 66, who had been for 24 years entirely dependent upon the catheter. I am glad to say this patient was recently—ten years after the operation—in fairly good health and able to retain and pass his urine naturally.

Jar containing 15 calculi, weighing ½ lb., removed from the bladder in Case 992. Actual size.

[illegible] off 32 ounces of [illegible] ity 1005, and con- [illegible] enlarged, dilated, [illegible] toms I decided to drain the bladder suprapubically before removing the prostate, so as to relieve the backward pressure on the kidneys and thus enable them to regain their functions.

Assisted by Dr. Tibbetts, I performed suprapubic cystotomy on April 30th, and found that the prostate presented a tongue-shaped [illegible] evious uræmic symptoms continued [illegible] hiccough supervened; but all these [illegible] that on May 14th, assisted by Dr. [illegible] the operation. The prostate, which [illegible] my urinary flow is perfect and my appetite splendid."

This is a typical example of one of the few conditions under which it is advisable to divide the operation into two stages, so that the uræmic symptoms may pass off and the kidneys regain their full excreting powers before removing the prostate. Had the gland been removed without preliminary drainage in this case, the shock to the maimed kidneys would probably have induced total suppression of the urine.

CASE 992.—A patient, aged 72, consulted me on July 22nd, 1912, on the advice of Dr. T. H. Machie, of Bognor. He had suffered from urinary symptoms for 20 years, during which he had from time to time

THE RECORDS OF FOUR UNUSUAL RECOVERIES IN CASES OF MENTAL DISEASE.

BY LEWIS C. BRUCE, M.D. EDIN., F.R.C.P. EDIN.,
MEDICAL SUPERINTENDENT, PERTH DISTRICT ASYLUM, MURTHLY.

THE records of the four following cases are of interest in so far that they demonstrate that even apparently hopeless cases of nervous and mental disease can never be safely pronounced incurable.

CASE 1.—The patient, a male, aged 30, labours under a mild type of imbecility, and was up to eight years ago a confirmed epileptic. His history states that his epileptic seizures commenced during infancy. When he first came under my care in 1899, and up to 1904, his epileptic seizures were very frequent, averaging between 200 and 300 each month. The fits were both diurnal and nocturnal. During 1904 certain serum observations were made in order to test a statement made by Ceni to the effect that the serum of epileptic patients when taken from the body develops certain antibodies which when injected subcutaneously into the patient yielding the serum, or into other epileptic patients, have a curative power. The patient being the most consistent sufferer from epilepsy under my care at the time was asked to give serum for the purposes of the observation. This he readily agreed to do. During a period of six weeks blood to the amount of 40 c.c. was drawn from the median basilic vein once a week, so that during the six weeks he yielded 240 c.c. of blood. The curious fact is this, that from the day of the first bleeding up to the time of writing—that is to say, during a period of eight years—the patient has never again suffered from a single epileptic seizure. I have often speculated whether his recovery from epilepsy was a coincidence or the result of the venesection. Similar venesection in other cases of epilepsy certainly did *not* improve the epileptic condition. It is to be noted that the patient never received an injection of his own or any other patient's serum.

CASE 2.—The patient is a woman who when she first came under my care was 57 years of age. She suffered from recurrent attacks of *folie circulaire* mania with barely recognisable periods of depression. Each of the attacks of excitement lasted about six weeks, with varying intervals of sanity. The history of her illness is as follows. Her first attack of excitement recorded occurred when she was 27 years of age. The first record of her admission to an asylum was in June, 1892, and she was discharged in September of the same year. She was readmitted in February, 1897, and redischarged in April of the same year. She was again admitted in August, 1900, and discharged in January, 1901. Her last admission, when she came under my care, was in October, 1901. During 1902, 1903, 1904, and 1905 she suffered from frequent attacks of mania, the onset of each attack being preceded and accompanied by an attack of nasal catarrh. She presented no other physical symptoms beyond a recurring hyperleucocytosis of from 12,000 to 20,000 per cubic millimetre which accompanied the attacks, and the presence of a specific agglutinin in her serum to a variety of streptococcus isolated by myself from the blood of a case of acute mania. Her opsonic index to the same organism varied between 0·4 at the commencement of an attack to 2 at the termination of an attack. Various attempts were made by means of injections of this streptococcus to produce immunity, but without effect, and no antibacterial substance could be demonstrated in her serum as the result of these injections.

In October, 1905, it was decided to try the effect of feeding the patient on living cultures of the streptococcus which her serum agglutinated. The organism was grown in sterilised broth for 48 hours at 37° C. and then dispensed in 10-ounce bottles, of which she took 1 oz. thrice daily between meals, and this course was continued for six weeks. During this period her appetite increased very markedly, and her weight went up from 10 st. 1 lb. to 11 st. At the end of the six weeks' course of treatment her serum was tested for immune body and was found to contain a specific bacteriolytic substance, which was demonstrated as follows. One part of a 24 hours' broth culture of the streptococcus was mixed with two parts of her serum; the mixture was drawn into a sterile pipette, which was sealed and placed in the incubator at 37° C. for three hours. A control of the serum of a healthy person was made at the same time. At the expiration of the three hours the contents of each pipette were spread on agar tubes and incubated. At the end of 24 hours' incubation it was found that in the tube inoculated from the patient's mixture of serum and broth culture there were only three colonies of organisms visible, while that inoculated with the pipette made from the control serum showed countless colonies. To prevent error the observation was repeated with a second control with the same result. From the date of treatment in October, 1905, to the date of discharge, December, 1907, the patient never suffered from another attack of mania, and up to the time of writing she has not had a relapse.

I naturally thought that I had hit upon a discovery in treatment, but this proved incorrect, as out of six other and similar cases so treated I obtained no satisfactory results, nor was bacteriolytic substance ever demonstrated in the sera of these patients. If this recovery was not the result of the feeding with streptococci, but a coincidence, then we must accept the presence of antibody in the serum as an indication of the method nature takes to arrest such conditions of disease. If, on the other hand, we accept the recovery as the result of feeding with bacteria, it is curious that other and apparently similar cases did not benefit by the same treatment.

CASE 3.—The patient is a woman aged 32. She developed melancholic symptoms, with fixed delusions and marked impairment of nutrition at the age of 30. She was treated for two years, partly at home and partly in an asylum, without apparent benefit, and was admitted to Murthly in October, 1908. Her nutrition was miserable; she was depressed, took no interest in her surroundings or personal appearance, and expressed fixed delusions. She presented no physical disorder beyond the condition of malnutrition, a dry harsh skin, want of appetite, constipation, and an irregular hyperleucocytosis of from 12,000 to 17,000 per c.mm., the increase being chiefly in the polymorphonuclear cells. All sorts of remedies were applied in her case; she was treated with thyroid, hot baths, injections of cinnamate of soda and various vaccines with practically no effect; the prognosis given in her case was most unfavourable. At the end of March, 1910—i.e., four years after the onset of her illness—she contracted scarlet fever. The fever was of a mild type with little constitutional disturbance, the highest temperature recorded being 101° F. As she convalesced from the fever a marked physical and mental improvement was noticeable, and by the end of April she had recovered. She was discharged at the end of May, 1910, and has shown no signs of relapse up to the time of writing.

I have seen an attack of scarlet fever in recent and hopeful cases of mental disease hasten recovery, but this is the only case I have seen of scarlet fever occurring in what was, to all intents, a chronic case of insanity.

CASE 4.—The last case is possibly the most interesting of the four. It is that of a woman, aged 27, who became insane in May, 1904, and was removed to a large city asylum. What the nature of the early attack was I do not know, but when she was transferred to Murthly, in November, 1904, she was a morose, impulsive, absolutely intractable woman. She suffered from delusions of identity, she had her own names for members of the staff and for some of her fellow patients, and she referred to these persons as to individuals whom she had known all her life. She fell into the routine of the house, in so far that she went to the dining-hall for meals, to church and social functions, but she could not be employed in any way. At frequent intervals she was impulsive, suddenly attacking fellow patients or members of the staff, and these attacks were, so far as one could judge by her disjointed speech during these outbursts, directly the result of the delusions of identity she laboured under regarding the persons she assaulted. No observations could be made with regard to her physical state on account of her impulsiveness, and no attempts at treatment met with success for the same reason.

No change was noted in her condition until May 5th, 1908, when she was reported as having been found in an unconscious state in her bed in the morning. Upon examination she presented all the symptoms of a cerebral hæmorrhage, being completely paralysed on the right side. When she recovered consciousness it was also noted that she was aphasic Following upon the seizure she developed a high *temperature, which ran as high as 104° F* , and this pyrexia, which was remittent in character, lasted for three weeks At the end of the three weeks the paralysis was passing off and the power of speech was returning Five weeks after the date of onset of the seizure she spoke to me quite clearly and collectedly. She asked where she was, how long she had been at Murthly, and how she came to Murthly Further *inquiries* elicited the fact that her mind was a perfect blank for a period of four years—that is to say, from the date of the onset of the attack in May, 1904, to the convalescence *from* her cerebral hæmorrhage in June, *1908* She *knew no one ; the medical* men, the nurses, and her fellow patients were to her complete strangers When she was able to get up and go about the ward she recognised nothing ; she had to be shown her way to the dining room, the chapel, and recreation hall, and she had no recollection of her violent and impulsive behaviour, and yet from her admission in November, 1904, she was apparently conscious, in so far that she knew what was said to her and obeyed orders Although she called the nursing staff by names of her own she never confused these names and she certainly knew her way to the dining hall, the recreation hall, and her own bed in the dormitory She made an excellent recovery, was discharged in July, 1908, and went into service Up to the present date she has not been readmitted into this asylum

Her mental states suggested a condition of dual personality, and to me it is quite inexplicable that an *apparently hopeless* case of insanity should suddenly recover as the result of a cerebral hæmorrhage followed by three weeks of almost hyperpyrexia

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND *THERAPEUTICAL.*

◆

NOTE ON A CASE OF OBSTINATE SCIATICA TREATED BY PHENAZONUM INJECTIONS

By LEWIS W REYNOLDS, M R C S ENG ,

SURGEON TO THE HIGH WYCOMBE COTTAGE HOSPITAL

THE *treatment of obstinate sciatica is attended* with so many difficulties that the success by Fubache's method may be *of interest*

The patient, aged 66, a man of robust constitution, weighing 15 st , came under my care on August 30th, 1912 He had had a sharp attack of sciatica in 1886 and was quickly cured by the baths of Hammam R'Irha, Algiers, again in 1905 he was apparently cured of another attack by visiting the same baths An attack in September, 1911, was greatly relieved by three weeks of Harrogate treatment—baths, massage, electricity, &c In June, 1912, after a sharp attack of lumbago a more severe trouble arose from a return of the sciatica Three weeks in Droitwich, baths, massage, and Aix douche, made the patient's condition steadily worse He returned home and took to his bed on Sept 3rd The
ctric light bath was tried, as well
of the sciatic nerve, *salicylates,*
other remedies but he continued
to experience the most acute pain on the slightest movement He could only lie on his left side, the sciatica affecting his right leg from thigh to foot On Sept 21st I commenced the deep hypodermic injections of the following phenazonum ʒ iiss , cocain hydrochlor , gr iiss , aq destill steril , ʒ iiss , 1 c cm (♏ xv) of the preparation being injected into the upper part of the thigh over the nerve These injections were repeated at different places along the course of the nerve on Sept 23rd, 25th, and 27th and on Oct 3rd, 7th, 9th, 13th, and 17th The injections caused no pain at the time, but invariably about six hours afterwards a great deal of pain was experienced, which lasted some hours and sometimes necessitated an injection of morphine There was no great relief from the treatment until Oct 12th, but the nearer the injection got to the nerve the greater the *relief seemed* to be For instance, the injection over the external popliteal behind the head of the fibula gave great relief, and another injection on Oct 13th on the dorsum *of the foot completely* removed the pain after four hours, and it has not returned After Oct 12th the patient rapidly improved , the pains ceased and movement became easy About this time some anxiety was felt because of some slight cardiac trouble, causing a slow and intermittent pulse, but a mixture of strychnine and digitalis put this right again Since
Oct 28th his habits, and
he only n his right leg

NOTE ON THE USE OF TUBERCULIN

By BERTRAM COHEN, M B , B S LOND ,

LATE HOUSE SURGEON, HOUSE PHYSICIAN AND ASSISTANT CURATOR, ST GEORGE'S HOSPITAL.

WHILE so much literature is appearing advocating on the one hand and criticising on the other the use of tuberculin in the treatment of pulmonary tuberculosis, the following case *may be of interest*

The patient, a man aged 21, was seen by Dr W F Colclough and myself for the first time on Jan 11th, 1913, complaining of abdominal pain over the region of the appendix The whole of the right side of the abdomen was *rigid and painful*, but there was diminished *resonance* and air entry into the base of the right lung On Jan 14th there was definite evidence of fluid in the right chest , the abdominal symptoms had disappeared, having been due to inflammation of the diaphragmatic pleura On the 17th the right chest was aspirated , 16 oz of clear fluid were drawn off, a good deal more being left to absorb The case was clearly one of tuberculous pleural effusion The temperature did not fall, varying in the evening between 100° and 101°, and the fluid showed no signs of absorbing On the 23rd the patient *was given 1/10000* T R *During* the next two days the temperature for the first time fell below 99° F On the 25th the evening temperature was 99 4° On the 26th 1/10000 T R was repeated The next day the temperature remained normal, but only to rise to 99 8° the day after This was because 1/10000 was too small , 1/8000 ought to have been given On the 29th he was given 1/7500 , the temperature at once dropped to 98°, where it remained until his discharge, not fluctuating more than 0 2 of a degree

The patient left hospital on Feb *10th* well and *markedly* improved in general health There is every reason to believe that if he takes tuberculin for the next six months he will not develop phthisis, in spite of the fact *that he has had* a tubercular lesion

I have found that the administration of tuberculin T R is of the utmost value in the treatment of pulmonary tuberculosis, and cannot too strongly emphasise the teachings of Dr Arthur Latham that the two cardinal rules are (1) start with a small dose , and (2) carefully watch the temperature, the amount of expectoration and clinical *symptoms*, and judge the time for giving and spacing of doses accordingly

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION.

Graves's Disease.—Appendicitis in Children.—Meningitis Serosa.

A MEETING of this society was held on March 27th, Mr. ROBERT JONES, the President, being in the chair.

Mr. COLIN CAMPBELL read a note on Four Cases of Graves's Disease treated by Fresh Thyroidectomised Goats' Milk. Reference was made to the mortality from disease of the thyroid (cancer excluded) in the Registrar-General's Reports. In 1900 the deaths numbered 227; in 1910 they had increased to 551. Neither Graves's disease nor exophthalmic goitre was mentioned in the reports, but Mr. Campbell had been officially informed that the number of deaths attributed to it was: in 1910, 390; and in 1911, 411. Obviously the disease was increasing and did not "tend to get well." Non-recovery was the rule, whilst deaths were more frequent than cures. His experience of the various sera had been unfortunate. The cases treated with fresh milk had improved comparatively quickly. One, he might say, was cured. It was possible that much of the benefit from the use of the goats' milk might be due to its nutritive qualities rather than to its antithyroid action.—Mr. C. THURSTAN HOLLAND had treated 50 cases of Graves's disease by X rays with satisfactory results, and thought that method much more reliable than any other.—Dr. W. B. WARRINGTON thought that Mr. Holland had made out a case for X ray treatment, but said that all remedies that had been tried and vaunted were ultimately found unsatisfactory.—Mr. KEITH W. MONSARRAT had seen surgical treatment very successful in properly selected cases. —Mr. E. T. DAVIES and Dr. J. R. LOGAN also spoke.

Mr. G. C. E. SIMPSON read a paper on Appendicitis in Children. In the records of the Liverpool Infirmary for Children there was no case of appendicitis, perityphlitis, or pericolitis recorded from 1876 to 1891, and from 1884 to 1891 only two cases of abdominal abscess led to a fatal result among an annual average of 15,000 patients. In 1892 a case of iliac abscess was recorded, and from that time there had been a steady increase in the frequency of these cases; in the last five years there had been an average of 24 cases per annum, the figure rising to 34 in 1910-11. The average death-rate was high, being 23 in 160 cases, or nearly 15 per cent. Mr. Simpson had himself treated 34 cases and urged that the disease was increasing in frequency and in severity, so that no opportunity should be lost of impressing on the public the importance of abdominal pain in a child. He urged on the medical attendant the advisability of early operation, as in children there was even less tendency to localisation of the disease to the appendix than in adults.—Mr. A. STOOKES said that while he had been resident at the Infirmary for Children in 1884 a case of abscess of the brain and liver had been recorded which was secondary to a pain in the vermiform appendix. He was much struck by the frequency of the disease now as compared with its great rarity 30 years ago. He thought these cases were not missed by the practitioner of those days. In Dr. West's book on "Diseases of Children," published in 1859, the author recorded four cases, and the description of the disease showed that he recognised its existence and its rarity. It was important that further work should be done to arrive at the cause of this increase in so fatal a disease.—Mr. R. W. MURRAY said he had read a paper 15 years ago in which he had advocated treating these cases by hot fomentations and temporising measures until the abscess pointed, and then opening and draining. He could not now value such a recommendation; the poison had increased in virulence, possibly due to food adulteration. He would emphasise the importance of abdominal pain in children.—Mr. F. T. PAUL said that in his early days he remembered only three cases of appendix disease in five years, during which every fatal case at the Liverpool Royal Infirmary was examined after death. He believed that there was always a foreign body in the appendix at the first attack, either a concretion or other body. It was essential to get the case early, but where the case was not seen at the very onset it was necessary to use judgment as to operation. In some cases he thought it wise to wait for an interval operation; no hard-and-fast rule could be laid down.—Dr. C. J. MACALISTER thought investigation was needed as to the cause of intestinal diseases, especially into food habits. He had been struck by the way in which some individuals seem to require an animal and others a vegetable dietary. Appendicitis was closely related to the other intestinal disorders, such as colitis, and he thought the condition of the teeth had much influence in these diseases.—Mr. ARTHUR J. EVANS drew attention to the fact that a right-sided basal pneumonia might be mistaken for appendicitis.—Mr. DAMER HARRISSON also spoke, and Mr. SIMPSON replied.

Dr. WARRINGTON read a paper on Meningitis Serosa, which he said was chiefly associated with otitis, but was also associated with other infective diseases, as tuberculosis. The term implied a condition in which there was a pathological collection of clear sterile fluid in the intracranial cavity. He related a number of cases associated with otitis media, and alluded to the earlier as well as to the later views on the pathology of the condition. The diagnosis from abscess of the brain was of much practical importance. The chief guiding marks appeared to be (1) the sudden and acute onset of symptoms with an otitis; (2) the fluctuating course of the symptoms; (3) the absence of constitutional signs often associated with brain abscess; and (4) a study of the localising signs which differ from those sometimes met with in abscess. He then described cases illustrating the occurrence of this condition in general infections and particularly in tuberculosis, where grave cerebral symptoms might appear and yet terminate favourably. He drew attention to the fact that serous exudates into the intracranial cavity might occur in association with distant sites of suppuration—e.g., after appendicitis and puerperal infection. Lastly, he mentioned instances following a blow on the head, or a mental shock, and described the clinical history of a case of "serous apoplexy" in a young man, occurring as the result of starvation and exhaustion and terminating in complete recovery.—The following took part in a discussion on the paper: Mr. A. ADAIR DIGHTON, Dr. T. R. GLYNN, Mr. H. E. JONES, Dr. J. OWEN, Professor E. E. GLYNN, Mr. DAMER HARRISSON, Dr. N. P. MARSH, and Dr. R. J. M. BUCHANAN.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Some Recent Conceptions of Hysteria.—The Toxæmias of Pregnancy.

A MEETING of this society was held on April 3rd, Dr. STANLEY RISELEY, the President, being in the chair.

Dr. A. G. YATES, in a paper on Some Recent Conceptions of Hysteria, discussed, firstly, the etiology of functional nervous disorders. This was obscure, because as yet no pathological changes had been found to account for them. This failure had in recent years led to an elaborate attempt to define the neuroses and explain their causes in terms of psychology. Symptoms were explained, not on the basis of physical changes in the tissues, but on that of abnormal mental functions. In referring especially to the work of Janet and Freud Dr. Yates said: Both assume the existence of subconscious mental processes. Janet argues that in the hysterical mind that portion of it which is concerned with conscious mental activity is quantitively diminished. It is not able to contain at one and the same time as many thoughts, feelings, or emotions as the normal mind. The expression "field of consciousness," is a convenient one to include the whole mass of ideas, sense impressions, &c., of which a person is at any one moment conscious. It might be represented diagramatically by two circles, one within the other. The inner circle would represent the particular idea, object, or feeling towards which the mind was at that moment directing its attention. In the outer circle, we might place all the other mental processes of which the mind was at the same moment conscious, but less distinctly. This is the peripheral portion of the field. We might extend our diagram still further by adding a third circle outside, to represent the subconscious portion of the mind. By such diagrams we could compare the normal with the hysterical mind, simply by making the circles representing the conscious field larger in the former than in the latter. In other words, a number of mental processes which in the normal mind are retained within the conscious portion are, in the hysterical individual, transferred to the subconscious area. Present sense impressions are often unable to gain admission into the diminished conscious area, with the result that anæsthesia is produced. In the hysterical fit the area of personal consciousness is not merely diminished, but for the time being obliterated, and the mind is dominated by some idea, impression, or event of the past. This mechanism is sometimes quite apparent, but not always. It seems probable, nevertheless, that this apparently meaningless paroxysm is the result of some idea or memory of the past, fixed within the subconscious sphere in a mind in which that sphere is abnormally active and large, but possessed of a diminished facility or outlet into the neighbouring sphere of consciousness. Such a fixed idea from time to time bursts its barriers, flows out with irresistible force, flooding the already diminished field of consciousness, takes complete command of the individual, and spends itself in a display of long pent-up emotion. All the other phenomena of hysteria which occur during the inter-paroxysmal period are likewise explained on the assumption of some fixed subconscious idea finding an outlet by these varied manifestations. Freud looks upon the condition as the result of some mental shock. The corresponding painful emotions, instead of gaining a suitable outlet, are repressed or driven down into the subconscious area of the mind, so that they are no longer felt. They are still active, however, and some outlet must be provided. This is effected by the conversion of these submerged emotions into the physical and mental phenomena which we know as the symptoms of the disease. By a method of treatment known as "psycho-analysis" Freud has been able to trace the connexion between some original painful emotion and such hysterical phenomena. It is a long and tedious process, but Freud believes that by analysing the enormous mass of ideas and chains of thought which he obtains he can discover the hidden cause of the symptoms, and claims that its revelation to the patient will effect a cure. These two theories resemble one another in assuming that the causative factor is some mental impression buried in the subconscious mind. Two cases were shown illustrating the rhythmical tremor of hysteria. In one case the left forearm had been partially paralysed from birth. It had, however, given no trouble until six months ago, when it became painful. Subsequently the tremor developed in it, and within the last few days it had also affected the other arm.

Mr. W. W. KING, in a paper on the Toxæmias of Pregnancy, said that these toxæmias often manifested themselves as disturbances of metabolism which could be recognised by urinary examination. The nature of the toxin was unknown, but it was probably composed of a number of different elements, as suggested by Leith Murray. Recent work also indicated that the internal secretions from the ductless glands were an important factor in toxæmic pregnancy. The early vomiting of pregnancy was not "physiological," and all but the mildest cases required treatment. The symptoms of pre-eclamptic toxæmia should be explained to all primiparæ. Glucose in the urine in pregnancy might be due (1) to diabetes; (2) to hypersecretion from the pituitary gland; (3) to inability of the liver to store up glycogen. The last type was of toxic origin and was often associated with headache, neuritis, or muscular twitchings. The glucose disappeared when the patient was placed upon a meat-free diet. A case of toxic post-partum jaundice with very severe vomiting, which followed slight toxæmic symptoms, was related as showing that even mild symptoms might develop into grave disease. Both infant mortality and morbidity were much increased in all forms of toxæmic pregnancy.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 4th, Mr. Henry Curtis, the President, being in the chair.—Dr. A. E. Stansfeld read a paper on Vaccine Therapy in General Practice. Proceeding from the assumption that vaccine therapy has already amply justified its existence, Dr. Stansfeld pointed out the ways in which the "boom" in vaccines has served to discredit their use in the production of immunity. They have been used in unsuitable cases; improper doses have been employed or the intervals of administration have been at fault; slovenly bacteriological methods have sometimes been responsible for failure, and in other cases older methods, to which vaccination should be merely an adjuvant, have been unfairly abandoned. After dealing briefly with the varieties of immunity and the nature of vaccines and immune sera, Dr. Stansfeld proceeded to consider (1) the general rules which determine the suitability of a case; (2) the methods of immediate procedure, culture, &c.; (3) the administration of the vaccine. Vaccine may be used for prophylaxis or for treatment, and in the former category such recurring diseases as nasal catarrh and boils will be of special importance in general practice. As regards suitability of cases for treatment, it must be remembered that although practically all kinds of infections are amenable, not all cases are suitable. Speaking generally, it might be said that the more localised and the more chronic the infection the more the benefit likely to be obtained from vaccine therapy. But there are exceptions to this statement, such as the B. coli infections of the urinary tract. Various common types of lesions were then considered with the amenability of each, illustrated by recital of cases. The importance of identifying the causal organism, the possibility of multiple infective foci, and the frequency of mixed infections were discussed. It was pointed out that special tests—e.g., the agglutination test—may be necessary to demonstrate the relationship of the bacterium isolated to the disease, and speculative use of vaccines was condemned. The methods of collecting material for cultures were dealt with and then the relative influence of vaccines prepared from the common and specific organisms. After considering the value of stock vaccines, Dr. Stansfeld described the use and special advantages of sensitised vaccines—viz., the complete absence of unfavourable reaction and of negative phase, and the superiority of the sensitised vaccine to the uncombined vaccine and corresponding serum used independently. The importance of adopting other methods of treatment, particularly local drainage and disinfection, was insisted upon. The initial dose of vaccine depends upon the acuteness or chronicity of the infection, the degree of localisation, the nature of the infecting organism, and the general condition of the patient. No exact rules are possible, because patients and organisms vary; the chief guide must be experience, and when in doubt it is well to err on the side of giving too small a dose rather than too large. Frequency of administration and the intervals to be allowed between successive doses again depend upon experience and upon the result of the first dose. In the case of sensitised vaccines, the absence of negative phase permits the use of large doses at frequent intervals, and ascending doses on three consecutive days are usually employed.—Dr. Leslie Durno emphasised the importance of local attention to the teeth in cases of pyorrhœa alveolaris; in his experience this, including removal of carious teeth, sufficed to cure most cases in a very short time. He thought extraction should be cautiously employed if alveolar abscess existed.—Dr. David Ross instanced a case in which extraction had been followed by a very severe reaction under these circumstances, and the President emphasised the inadvisability of extracting a tooth when an alveolar abscess is pointing through the jaw.—Dr. T. S. Maynard considered the treatment of chronic cases of B. coli cystitis.—Dr. J. R. T. Conner referred to treatment by production of "fixation abscess."

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at 59, Leicester-square, on March 18th, Dr. Morgan Dockrell being in the chair.—Mr. E. H. Ross read a paper on the Intracellular Parasites in Syphilis and in Allied Conditions in Animals, in which he said that he had found intracellular protozoal blood parasites in a large percentage of guinea-pigs examined; another species of the same genus of protozoal parasite had been found in earthworms. He had also described similar intracellular parasites in every untreated case of syphilis in the human subject he had examined, and some of these had been observed to develop into spirochætæ. They had been found in the chancres, buboes, *condylomata*, secondary sores, skin rashes, and in the peripheral blood during the acute stages of the disease. Mr. Ross also mentioned that rabbits and hares suffer from a disease indistinguishable from syphilis.—The President spoke of the results of his observations on patients after giving salvarsan—viz., that they obtained a complete freedom from the parasites for a time, but they returned before long and that it was necessary to continue with mercury.—Dr. W. Griffith considered that from a practical point of treatment it might be well to examine the blood of patients for these amœboid bodies, and only give salvarsan when they and the spirochætæ were found free in the blood.—Dr. W. Knowsley Sibley said the paper confirmed the views he had always maintained. The fact that the same organism was found in earthworms suggested to his mind that the origin of the syphilitic virus was mother earth.—The following cases were shown: The President showed a woman, 35 years of age, who had had a peculiar lesion on the bridge of her nose for some two years which he was inclined to consider was a rhinoscleroma.—Dr. Sibley exhibited a case of Lupus in the Inner Canthus of the Right Eye in a man of 28 years, who had had it for four years. He had treated it with one application of carbon dioxide snow for two minutes and had obtained a very good result.—Dr. J. L. Bunch showed a case of a girl, 17 years of age, with an obvious Dermatitis Artefacta lesion on the leg.—Dr. Griffith exhibited a case of Mycosis Fungoides in an old man, and the case of Crocodile Skin he had shown on a previous occasion, and one of Circumscribed Prurigo.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on April 2nd.—Dr. H. B. Fantham, of the Liverpool School of Tropical Medicine, read a paper on Some Recent Researches on Sleeping Sickness, Spirochætosis, and Amœbic Dysentery. He dealt first with human trypanosomiasis, especially with the recent work on the Rhodesian parasite (Trypanosoma rhodesiense, Stephens and Fantham), and the characteristics of the disease as seen in cases from Rhodesia and Nyasaland. The discoveries of Kinghorn and Yorke in determining the vector (Glossina morsitans) and the reservoir in big game were discussed, together with the significance of the developmental period of the trypanosome in the fly. The habits and breeding places of Glossina morsitans in contrast with the more restricted ones of Glossina palpalis were noted, and the recent methods of drug treatment were mentioned. The occurrence of a human trypanosomiasis in Brazil was referred to. This section of the address was fully illustrated by lantern slides, specimens showing the life cycles of glossinæ and microscopic preparations. Regarding spirochætosis, the life cycle of S. duttoni and its stages in the tick Ornithodorus moubata were briefly dealt with and illustrated by specimens and slides. Mention was made of the recent work on spirochæta recurrentis in lice (pediculus vestimenti) by the French investigators in Tunis. In connexion with amœbic dysentery the importance of the study of Entamœba tetragena was emphasised, and this organism was briefly compared and contrasted with E. coli and E. histolytica. Lantern slides illustrating these amœbæ were shown together with a smear containing E. tetragena.

THE MILK SUPPLY.—A special meeting of the council of the Charity Organisation Society will be held at Denison House, Vauxhall Bridge-road, on Monday, April 14th, at 4.30 P.M., when Mr H. Dixon Scott, honorary treasurer of the Pure Food and Health Society of Great Britain, and Mr. Wilfred Buckley will speak on "The Best Means of Increasing the Supply of Pure Milk"; and Dr. Reginald Dudfield, medical officer of health to the metropolitan borough of Paddington, will speak on "The Supply of Suitable Milk for Infants."

DONATIONS AND BEQUESTS.—By will the late H. G. Anderson has bequeathed £1000 to the Arbroath Infirmary and £500 to the Convalescent Home connected with it. The testator also left £500 to the British Hospital at Montevideo.—The late Mrs. Elizabeth Akrill, of West Bromwich, has left £10,000 for the erection and endowment of a convalescent home for women and children, or a home for crippled children, or for both purposes.—Subject to some life interests the late Mr. H. Goddard, of Brixton Hill, has left about £18,000 to the Brixton, Streatham Hill, Tulse Hill, and Herne Hill Dispensary.

Reviews and Notices of Books.

The Principles and Practice of Medicine, designed for the Use of Practitioners and Students of Medicine. By Sir WILLIAM OSLER, Bart., M.D. Oxon., F.R.C.P. Lond., F.R.S., Regius Professor of Medicine, Oxford University, &c. Eighth edition, largely rewritten and thoroughly revised, with the assistance of THOMAS MCCRAE, M.D., F.R.C.P. Lond., Professor of Medicine, Jefferson Medical College, Philadelphia, &c. London and New York: D. Appleton and Co. 1912. Pp. 1225. Price 21s. net.

AMONG the many causes of the sustained and deserved popularity of Professor Sir William Osler's well-known text-book of "The Principles and Practice of Medicine," the most important are the regularity and efficiency with which it is revised and brought up to date, so as to afford a carefully weighed and digested account of much new work of recognised importance. We are told in the preface that it is 20 years since the appearance of the first edition, and that comparing the first with the present very little remains of the original work. It still retains, however, the clear arrangement, the broad outlook, and the lucid, incisive style of its distinguished author, which have made it one of the most widely read text-books for nearly a generation. Dr. Thomas McCrae has revised the sections on treatment and on diseases of the organs of locomotion in the present edition, and has also seen the work through the press. Dr. A. G. Gibson, of Oxford, has helped in the rewriting of the section on the heart and arteries, while Dr. H. M. Thomas and Dr. Harvey Cushing have assisted in the revision of the section on nervous diseases.

The chief changes made in this edition are that the infectious diseases are grouped in a different order, and those of which the specific germs are doubtful or undiscovered are considered separately at the end of the section. The chapter on enteric fever has been brought up to date, and is one of the most informing and practical accounts of this disease with which we are acquainted. A new chapter has been added dealing with the colon bacillus infections, which are considered after enteric fever. These are divided into general hæmic infections, subinfections, and local infections. Unfortunately, little or no attention is given to the treatment of these conditions. In connexion with typhus fever, mention is made of the work of Nicolle, Anderson, and Goldberger who have been able to transmit the disease to monkeys. The pneumonias and pneumococcic infections are grouped together, and are considered in a very clear and authoritative manner. The description given of tuberculosis is brought up to date, and much new matter is incorporated, especially in regard to pathology. The discussion of the treatment is critical and practical, and in regard to the use of tuberculin Sir William Osler is very wisely cautious and scientific. We would specially draw attention to his warning that its indiscriminate use renders an estimation of its value very difficult. In regard to syphilis, an interesting summary of the administration of salvarsan and its uses is given, with a brief description of the types of case for which it is suitable. Among the new sections introduced into this edition we may mention those dealing with leishmaniasis, the sporotrichoses, pellagra, ochronosis, and hæmochromatoses. An interesting account is also given of caisson disease and of its pathology and treatment.

The eighth edition of Sir William Osler's text-book will fully maintain the reputation of its predecessors. We can cordially recommend it as a comprehensive, critical, and practical work, both for the student and the practitioner.

The Surgical Diseases of Children. By W. F. CAMPBELL A.B., M.D., Professor of Anatomy, Long Island College Hospital, Surgeon-in-Chief, Trinity Hospital, &c.; and LE GRAND KERR, M.D., Attending Pædiatrist to the Methodist Episcopal and other Hospitals. London and New York: D. Appleton and Co. 1912. Pp. 693. Illustrated. Price 25*s.* net.

THE surgery of childhood presents its peculiar problems and difficulties, not merely because of the smaller anatomical relationships, but because the surgeon is called upon to consider the effect upon development and growth that follows all surgical procedures in a child. "The authors, therefore, feel that a distinct advance in this field is possible only as the surgical diseases of childhood are viewed from both the standpoints of the surgeon and the pædiatrist. Again, the surgery of childhood imposes a heavy responsibility upon the family physician—it is always his problem first, before it is shifted to the shoulders of the specialist." It is apparently owing to these considerations that we have the present work, in which two authors have collaborated and which is dedicated to "the family physician."

The authors have treated the surgical diseases of children in a systematic way. Beginning with general considerations and going on to the examination of the child in regard to posture, gait, and pain, they come to deal with the various surgical affections and injuries in order and in detail. This concludes Part I. in 9 sections and 43 chapters. Part II. is occupied with regional surgery, bringing the total chapters up to 80. There is a useful index. All that the authors write is sound and up to date, and therefore differs little from what is to be found in the text-books of European currency. It would be tedious to refer to the many well-known expedients for the better treatment of children that have found their way into use in recent years, for surgeons all over the world are doubtless quite familiar with most of them. We have rather looked for the banishment of old and worn-out methods, and are surprised to find that the use of the plaster-of-Paris jacket for the ambulatory treatment of spinal caries finds a place in this book. In fairness to the authors we must state that they write of it in a tone of no special approval. We should have preferred the omission of the method. Scattered throughout the work are many remarks of a peculiarly practical character indicating a close personal acquaintance with the conditions described, and there are one or two sections which will be found very useful by the general practitioner; notably that on the surgical signification of pain, which is a chapter full of information. On the other hand, the sections on the production of anæsthesia and on the use of X rays in surgery are scrappy and of little real use. These subjects are much too important to be dealt with in a chapter of a book like the present.

In regard to the illustrations they are on the whole clear and good, and when they are photographs of real conditions they are unexceptionable, but we have no great love for diagrammatic photography, and to look upon the photograph of a child with an eager, penny-expectant face, supposed to be suffering acute visceral pain under a shaded skin area, is to gaze at an incongruity. In many places the construction of sentences is loose and ambiguous, and we have noticed a few grammatical errors. Where there is loose construction only it is not difficult to gather the authors' meaning, but in some instances they lead themselves to say what obviously they do not mean; as, for example, on p. 157, when discussing the status lymphaticus: "When the child becomes the victim of an apparently very trivial inflammation or injury there is a very great and disproportionate *resistance* to injuries and inflammations in particular, and to all disease in general." These may be thought to be small and unimportant blemishes in an otherwise good book. Nevertheless, they are to be noted out of consideration for the many other good books at our disposal on the same subject.

We recommend this book to the American family physician, not, indeed, as enabling him to undertake himself all that it describes, for it is hardly full enough for that, but rather as showing him how much can be done for the cure of disease, or the correction and prevention of deformity, in a child by surgical methods.

Malingering and Feigned Sickness. By Sir JOHN COLLIE, M.D. Aberd., J.P., Medical Examiner, London County Council. Assisted by ARTHUR H. SPICER, B.S. Lond., D.P.H. Illustrated. London: Edward Arnold. 1913. Pp. 352. Price 10*s.* 6*d.* net.

Sir John Collie's small volume, published last year by Messrs. Baillière, Tindall, and Cox, on "Medico-Legal Examinations and the Workmen's Compensation Act, 1906," together with various lectures and published papers by the same author, has already afforded valuable hints to members of the medical profession as to methods by which the simulation and exaggeration of disease and of the alleged effects of accidental injury may be detected and proved. The subject, however, is of growing importance, and a more serious and exhaustive treatise on the subject, such as that which Sir John Collie has now compiled, should be welcomed by a large class of medical men with less experience than his in a branch of medical practice which he has made particularly his own. He does not write, however, exclusively for medical readers, and apologises quite unnecessarily for explanations and an absence of medical terminology which should increase the usefulness of his work. He has, in fact, embodied a large number of reports written for public bodies and insurance companies, and has had in his mind the possible usefulness of his book to members of the legal profession and to those responsible for the administration of the National Insurance Act.

Such a volume should be capable of comprehension by a wide public, and we hope that it may find a place in judicial libraries. It should also be instructive to employers of labour who are interested no less than insurance companies are in checking the dishonest practices which Sir John Collie describes. After all, it is the employer of labour who, so far as workmen's compensation is concerned, is most directly interested in the prevention of malingering. Insurance companies can recoup themselves by demanding higher premiums, safe in the knowledge that insurers must have recourse to those whose financial status promises security rather than to those who underbid in the desire to attract business; and if a general lesson for laymen may be extracted from Sir John Collie's writings it is to the effect that the most insidious malingerer may one day be caught off his guard by an observer who need not necessarily be equipped with scientific knowledge. We have spoken of the book as calculated to be useful to lawyers, and we may mention that the author combines with a power of stating lucidly facts and law a grasp of legal principles and a habit of eliminating the irrelevant not always to be found in the writings of those who, without having had the advantage of a legal training, deal with legal questions affecting professional duties.

The perusal of the wiles that may be employed to lure the suspected malingerer on to the performance of some act which in his supposed condition should certainly be impossible leads us to speculate how far unscrupulous solicitors, or for that matter unscrupulous medical practitioners—both of which classes we are presuming to exist—will be likely to use the book to "coach" client or patient as to what must be avoided. We can imagine such a legal adviser earnestly impressing upon his client the necessity for ceaseless watchfulness in playing his part, and entreating him if the ingenuous examiner drops a pencil not to forget his stiff back and stoop to pick it up, or reminding him that when he has once stated that he cannot raise his hand above his shoulder he ought not to betray himself by pulling off his own jersey in the usual way when asked casually to undress. We fancy, however, that even thus coached the malingerer would be found ultimately giving away his case in his increased apprehension of the pitfalls about him.

The arrangement adopted in the work is simple and practical. General chapters on malingering, on its prevention, and on medico-legal examinations as considered apart from any particular allegation of disability, are followed by others devoted to special topics of frequent recurrence, and requiring special consideration in sifting truth from falsehood. The establishment of the truth, on whichever side it may lie, is, it must always be remembered, the primary object of the examiner, and Sir John Collie holds no brief against the working man; on the contrary, he avows his recollection of and admiration for deeds of fine independence and sufferings nobly borne, but does not revert to them after his preface because they are not relevant to the subject matter. A consideration of special forms of malingering, which include the tests recommended in cases of alleged ear and eye trouble, and for the examination of the back, as well as the uses to be made of X ray photography, is followed by chapters discussing the effects of the Workmen's Compensation Act and the National Insurance Act; and some practical observations upon the preparation of medical evidence and the position of the medical man with regard to allegations of libel and slander are added. There is a chapter which touches the fringe of a subject of great importance in connexion with all forms of compensation for injury. "Accidents where pre-existing disease is present" have received practically no attention at the hands of the legislature in the imposition of heavy liabilities upon employers, by means of Acts of Parliament couched in terms of the most general description, and employers undoubtedly have suffered unjustly thereby. The questions of liability which arise in this class of case, and the question of the limitation to liability which justice should impose, are interesting French writers at the present moment, and may some day receive with us the recognition which their importance deserves. Reference should be made to the useful and practical chapter at the end upon electrical testing, for which the author acknowledges indebtedness to Dr. Christine Murrell. The book is copiously illustrated throughout.

The Surgery of the Rectum for Practitioners. By Sir FREDERICK WALLIS, M B., B.C. Cantab., F.R C.S. Eng., Surgeon to Charing Cross Hospital, St Mark's Hospital, and the Grosvenor Hospital for Women and Children. London: Henry Frowde and Hodder and Stoughton. 1912. Pp. 355. Price 15s. net.

UNFORTUNATELY the author did not live to see the issue of this, the second, edition of his book; he corrected the last proofs only a few days before he died. His book had already achieved a position in the literature of surgery, and this new edition would have enhanced his reputation. It is eminently a practical book, though theory is by no means neglected. It contains just those things which the general practitioner wishes to know about the diseases of the rectum, and the striking illustrations render the descriptions easily comprehensible. A good account is given of the anatomy of the rectum and also of its development—matters of importance in connexion with the surgery. As is well known, the author held that pruritus ani is commonly associated with ulceration of the rectum, and the correctness of this opinion is shown by the fact that treatment based on it will in many cases lead to a cure of the itching.' He did not claim that an ulcer was always the cause, but he urged that it should always be sought for.

We know no work on the surgery of the rectum better suited for those who have not devoted special attention to this branch of surgery.

The Nutrition of the Infant. By RALPH VINCENT, M.D. Durh. Fourth edition. London: Baillière, Tindall, and Cox. 1912 Pp. 343. Price 10s. 6d. net.

IN the present edition of Dr. Ralph Vincent's book on the nutrition of the infant, although a number of new arguments have been adduced for the exclusive use of unboiled milk as a food for artificially fed infants, the general spirit and arrangement of the book are on the now familiar lines The particular modification of milk to which Dr. Vincent gives the name of "fat-whey," and which is adapted for home use, is fully described in Chapter IV., where the printed directions, supplied to patients attending at the Infants' Hospital, for preparing this highly complicated mixture are given in detail. These directions are more suitable for middle-class mothers who should not rely on charitable institutions for medical treatment. The use of a dried whey powder, which is cheaper to employ than home-made whey, would obviate this difficulty.

An important argument for the use of raw milk is given in the chapter on the bacteriology of milk, and the sequels that await the operations of the physician who has not mastered the particulars are given here in all their lurid details. According to Dr. Vincent the chief bacteriological rôle in the processes of digestion in the infant is played by the streptococcus lacticus. This micrococcus is active only in the small intestine, and it is an obligatory fermentative bacterium—that is to say, it is not a facultative proteolytic bacillus like the bacillus acid lactici. Heretofore its presence and the importance of its functions have escaped notice, owing to the fact that it does not grow on ordinary nutritive media. This is, according to the author, the life-saving bacterium which we destroy when we boil milk, and this is the reason why infants fed on boiled or heated milk develop rachitis and all the other gastro-intestinal conditions which swell our infant mortality tables. One difficulty in accepting these views is that in Paris, New York, and other large cities where sterilised milk has been supplied on a large scale the infant mortality rate has been notably reduced. "It would appear," says Dr. Vincent (p. 168), "to be established that a fresh supply of the streptococcus lacticus in a faintly acid medium, such as milk, is an essential requirement of the infant." If this is so, how can the infant fed on recently boiled milk survive?

Although we find somewhat extreme the importance that Dr. Vincent attaches to the rôle of the streptococcus, in contradistinction to that of the bacillus lactis aerogenes and the bacillus acidi lactici, it is quite right that the attention of the medical profession should be drawn to the activities of a micrococcus which undoubtedly has an important place in the bacterial flora of the intestine, and to which heretofore too little attention has been given. But needful as it is to understand the essentials of percentage modification of milk—indeed, without such knowledge it is doubtful whether anyone can conduct the scientific feeding of infants—it must be remembered that in America, which is the home of the method, the practice of laboratory feeding and its nearest counterpart in home modification is rapidly dying out. And, further, it is worth while reminding ourselves that America, a country which spent such vast sums of money in securing a pure supply of milk which could be safely given to infants without boiling, is now boiling the pure milk which it has been at such infinite pains to procure. We cannot help thinking that Dr. Vincent is championing a somewhat unpromising cause.

Radioactive Substances and their Radiations. By E. RUTHERFORD, D.Sc., Ph.D., LL.D., F.R.S., Professor of Physics, University of Manchester. Cambridge University Press. 1913. Pp. 699. Price 15*s.* net.

THIS is the production of one who is master of his subject. Familiar as one may be with the researches of Professor Rutherford in the field of radioactivity, it is not until this book is perused that it is possible to realise the enormous amount that he has done in this new and important branch of science. This work, for example, greatly supplements his previous publication "Radioactivity," the last edition of which appeared in 1905. Since that time many new discoveries have been made, including a number of radioactive substances. In 1905 20 of these were known; there are now 32, and others are likely to appear in the future. While the book is rather outside the scope of the medical practitioner who has not been specially trained in physics, it will appeal strongly to the student of pure science, and there are some chapters that will afford interesting reading for anyone who is concerned for the future of medical science, even though he have not enough of the mathematical faculty or technical knowledge to follow the whole text. The first six or eight chapters are particularly recommended from the latter point of view, also Chapters XIII. and XIV., dealing in particular with radium, and Chapter XIX., on the radioactivity of the earth and atmosphere.

Though the book is intended more for the physicist than the physician, the latter may well be urged to read it. He will learn much from its perusal and have the satisfaction of feeling that his interesting knowledge is obtained from the latest authoritative work on a fascinating subject.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. Lieferung 29. Band I. *Physiologie der Atmung.* Zweite Hälfte. Bogen 21–30. Pp. 321–480. Lieferung 30. Band III. *Physiologie des Energiewechsels.* Erste Hälfte. Pp. 485–644. Lieferung 31. Zweite Hälfte. Pp. 625–786. Each part 5 marks. Jena: Gustav Fischer. 1912.

THE whole of Part 29 is from the pen of Professor Babák, of Prague, who deals first with the mechanisms and innervation of the aquatic arthropoda. Then follows a particularly interesting account of the tracheatæ and the marvellous adaptations of the mechanisms concerned in the process of respiration in insecta generally. Even when the concluding page is reached the author is still in the midst of his exposition of the respiratory arrangements and the nervous mechanism controlling the respiratory processes in beetles. Naturally the work of Plateau is largely drawn on, but the author adds a large amount of his own original work to the already colossal amount of details in regard to insect respiratory processes generally. We commend most heartily Professor Babák's contribution to the attention of zoologists and comparative physiologists as an exceptionally interesting and detailed exposition of the beauties of mechanical adaptation in articulate animals in regard to the all-important process of respiration.

In Part 30 Professor Biedermann continues his elaborate exposition of the supporting and skeletal tissues. A very full exposition is given of the supporting and mechanically protective structures in the protozoa, such as foraminiferæ and radiolarians, with a wealth of detail that can appeal only to professed zoologists. Then follows an equally thorough and minute account of all that relates to the skeletal tissues of sponges and echinoderms. The wealth of chemical, physiological, and morphological details is almost overwhelming. Towards the end of this part the author proceeds to give an account of the hard parts of the corals. Thoroughness is the measure of the author's endeavours, and he has succeeded both in regard to the matter of the text and the illustrations.

Part 31 contains the continuation of Professor Godlewski's contribution on the Physiology of Reproduction on such subjects as secondary sexual characters of the female and their relation to the genital glands, the inner secretion of the ovaries, hermaphroditism, normal and abnormal. Then follows a very full account of the changes that accompany maturation of the ovum and a rather elaborate description of parthenogenesis. Insemination and its equivalent in the lower invertebrates are next considered. The extraordinary arrangements in some of the lower invertebrates connected with the act of copulation are described and figured, the account of this process in worms and in certain mollusca, such as helix pomatia, being particularly full. Arthropoda are next dealt with. In this chapter, as in the others, the illustrations are a marked and useful feature. This brings the author to the vertebrates. A short account (about 16 pages) is given of similar events in fish, amphibians, reptiles and birds, and mammals. This part ends with a short account of ovulation and artificial impregnation—a process first practised by Spallanzani on frogs.

Forensic Medicine and Toxicology. By C. O. HAWTHORNE, M.D. Glasg., Lecturer on Forensic Medicine in the London School of Medicine for Women. Third edition. London: Edward Arnold. 1912. Pp. 344. Price 6*s.*

IN reviewing a third edition of a work but little need be said in regard to its general scope and nature. Dr. Hawthorne has presented in a convenient and classified form the principles and practice of forensic medicine as these concern medical students and practitioners. The various facts are set out clearly and succinctly, and students preparing for the ordinary pass examinations will find all the information they require put in a suitable form.

As a short work of reference practitioners can with advantage consult its pages regarding the main points in medico-legal cases where they may be called upon to testify. Attention may be especially directed to the chapters dealing with medical evidence and reports, documentary evidence, professional confidences, and similar subjects which are constantly presenting themselves as matters of difficulty in actual practice where a medical man's evidence is required. The portion of the volume devoted to toxicology will also be found of interest. Dr. Hawthorne has refrained from quoting illustrative cases; this procedure renders it possible to decrease the size of the work, an advantage that, in our opinion, compensates for any loss of interest. The present edition has been carefully revised and to a large extent rewritten.

Grundriss der Psychiatrischen Diagnostik, nebst einem Anhang, enthaltend die für den Psychiater wichtigsten Gesetzesbestimmungen und eine Uebersicht der gebräuchlichsten Schlafmittel. Von Professor Dr. RAECKE, in Frankfurt a.M. Mit 14 textfiguren. Dritte vermehrte und verbesserte Auflage. Berlin: August Hirschwald. 1912. Pp. 188. Price 3 marks.

THIS is an excellent little compendium of psychiatrical diagnosis. Both from the neurological and the purely psychiatrical standpoints the information it presents in small compass is accurate and comprehensive. The book is thin and will easily slip into the pocket; it is well printed and well arranged, while a good index renders easy the finding of any special subject. In the first section the conduction of an investigation into the patient's physical and mental states is described, and no detail appears to have been omitted. The student will here find practical methods of examining the state of the patient's intelligence; Jung's association tests are explained and exemplified, also Heilbronner's picture methods. Binet's scheme for the examination of children of each year from 3 to 12 is given in its entirety. There is a useful section on the simulation of nervous and mental symptoms. The second part of the compendium is taken up with brief descriptions of various types of mental disease, largely following Kraepelin's classification; the main symptoms are arranged so as to facilitate diagnosis. An appendix contains an abstract of German law as it affects the psychiatrist, and a useful summary of the chief drugs in vogue for the treatment of sleeplessness in the insane.

LIBRARY TABLE.

Heredity and Memory. By JAMES WARD, Sc.D., Professor of Mental Philosophy in the University of Cambridge. Cambridge: At the University Press. 1913. Pp. 56. Price 1*s.* 6*d.*—The author is of opinion that in the consideration of the problem of heredity psychology may show us that its secret may be found in the facts of memory, provided we look at the world from a spiritualistic and not from the usual naturalistic standpoint. A large part of the work is occupied with a lucid and powerful criticism of Weismann's hypothesis, and an alternative "mnemic theory" is set forth, according to which the germ cell is a definite unity, the counterpart of the structural alterations wrought by habit in the parental organisms with which it has been in sympathetic rapport all along. It is potentially the latent entelechy of a future organism. There is no ground for separating organic from psychical life; all life *is* experience. It cannot be assumed that experience has no part in the building up of the organism and begins only when a viable organism is already there. For the author ontogeny and heredity are aspects of a single process—a process that only experience will explain. The mnemic theory requires not merely physical records or "engrams," but living experience or tradition, and it will work for those who can accept a monadistic or pampsychist interpretation of the beings that make up the world.

International Clinics. Edited by HENRY W. CATTELL, A.M., M.D., Philadelphia, in collaboration with many others. 4 vols. London and Philadelphia: J. B. Lippincott Company. 1912. Price 35*s.* net the four.—The fact that articles appear in one or other of the four volumes of this useful quarterly publication by authors whose names carry real scientific and professional weight in this country and in the United States sufficiently indicates the quality of the work. It is impossible to review such a publication as this. To do so adequately would demand a critical examination of most of the 107 separate articles contained in the four volumes. It is sufficient to say that they embrace practically all the subjects that go to make up the field of medical science, and include articles also on certain subjects in medical economics, history, and biography. They are well illustrated with cuts and half-tones.

Astonishing Anatomy! By TINGLE. Vol. I., Part I., Fasciculus I., Section A (being Vol. II., Pt. VII., Fasc. III., Sect. F, of the Revised 1912 Edition, also Vol. V., Pt. IV., Fasc. X., Sect. S, of the 1911 Edition (New Series), and Vol. XI., Pt. II., Fasc. VIII., Sect. O, of the Abridged 1910 Edition). Fully illustrated by numerous woodcuts, abrasions, finger-prints, and thumb-nail scratches. London: Sir Isaac Pitman and Sons. 1913. Pp. 86. Price 1*s.* net.—The title should warn the reader to a certain extent what to expect—namely, a skit, and not an appreciation of the wonders of morphology. A note facing the title page advising the reader that by moistening the cover of the book and sprinkling it with mustard an efficient plaster will be obtained should confirm the impression. Such testimonials as "Quainter than *Quain*," and "I know no better anatomy—*Eugen Cocoa*"; and such *errata* as "For 'previous rotten' accounts" read "previous *written* accounts," and for "equally eminent authority" and "valued contributor" insert "*author* in each case," should make the impression a certainty. The contents of the book are extremely funny, and we can make no attempt to select anything as more particularly deserving quotation than anything else. The same difficulty we remember to have occurred when attempting to review "Wisdom while you Wait," a masterpiece which has obviously formed the model for the author of "Astonishing Anatomy."

Clinical Studies for Nurses. By CHARLOTTE A. AIKENS, formerly superintendent of Columbia Hospital, Pittsburg. Second edition. Illustrated. London and Philadelphia: W. B. Saunders Company. 1912. Pp. 569. Price 10*s.* net.—The purpose of this volume does not differ greatly from that of "Primary Studies for Nurses" by the same writer, the first volume of the series of which this is the second. It is designed to assist in securing graded instruction for nurses; to simplify and systematise the problem of teaching; to promote uniformity; to save time for teachers and pupils, and also to serve in some measure as a handbook for the nurse who is already trained and at work away from the training school or hospital. The writer has gathered into a volume matter previously published separately and dealing with subjects often very unsystematically taught by lecturers. The work aims to include the main points about the commoner diseases and their management, which a nurse must know if she is intelligently to assist the physician. The author thinks that no general training in nursing should be considered complete which does not include both theoretical and practical courses in obstetrics, as every nurse should know how to deal intelligently with obstetric emergencies. The desirability of providing during the last six months of the course for at least half a dozen class periods relating directly to private nursing is insisted on, as is also the importance of lessons in the ethical and business principles which should guide a nurse in applying for a hospital position. The need of a reference library for nurses in every nursing institute or training school is emphasised, and the writer furnishes a list of useful books of reference. This work will be useful to those interested in the training of nurses.

MISCELLANEOUS VOLUMES.

THE practical pursuit of archæology demands a considerable amount of leisure and a purse whose fulness is in direct ratio to the ardour of the possessor, but as a hobby and as a means of recreation during leisure hours and periodical holidays there are few occupations which can give such profitable results for a small amount of expenditure in money. In whatever manner archæological study is approached the subject appeals to the votary either with world-wide or only local opportunities in a useful manner, for an appreciation of the past is, in our modern excessive hurry, of real psychotherapeutic value. Archæology, too, covers a very wide field, and its different branches will appeal to minds of many moulds. In *Rough Stone Monuments and their Builders*, by Dr. ERIC PEET (London: Messrs. Harper and Brothers. 1912. Pp. 172. Price 2*s.* 6*d.* net), one of these branches is briefly but adequately dealt with, and the little book, which is one of Harper's Library of Living Thought Series, is exactly the kind which the casual student requires, while the more serious investigator will no doubt be glad to have in concise form a sketch of our present knowledge of megalithic monuments A fairly full account of these monuments in Great Britain and Ireland is contained in the introduction and two following chapters, the succeeding chapters dealing with Scandinavia, France, Spain, Portugal, Italy, Africa, Malta, and the dolmens of Asia Lastly, the writer discusses the builders of the monuments and their habits, customs, and religion, who they were and whence they came, inclining to the theory that megalithic builders were one race whose work was spread far and wide owing either to trade influence or migration What that race was is a problem which may never be solved

The pestilent character of the common house fly as a patron and fomenter of all that is filthy, unsavoury, and insanitary, and as carrier of infection and disease, while well known nowadays to medical men and scientists, and to some extent to cultured people generally, is still unknown to the great mass of the people We reviewed in THE LANCET of August 17th 1912, an excellent book by L O Howard on the subject, but such a book would not find its way among the populace generally and, if it did, it would be above their heads We welcome, therefore, a useful pamphlet by Mr ERNEST E AUSTEN, of the British Museum, on *The Housefly as a Danger to Health* (London British Museum (Natural History), Cromwell road 1913 Pp 11 Price 1*d*), which describes, with excellent illustrations, the breeding places and life history of the insect, the relations of house flies to disease, with some account of the remedies and preventive measures that can be used against them The medical practitioner especially may find this penny pamphlet of service in emphasising the importance of keeping the troublesome creatures out of the sick room and the kitchen ——The evil influence of the mosquito in helping to bring about racial degeneration has of late been the subject of scientific consideration, while the practical hygienic results of the extermination of this pest have been demonstrated in many places, and nowhere more conspicuously than on the Isthmus of Panama But in mosquito ridden localities that have not the advantage of being under military domination the public *must work out its own salvation, and for this popular* instruction in the relation of the pestiferous insect to disease and the methods by which it may be destroyed, is essential We have noted already several books designed and suited for that purpose, to which must now be added Dr ALVAH H DOTY'S *The Mosquito* (London and New York D Appleton and Co 1912 Pp 79) It is so written as to give all necessary information in popular language

Dr J JOHNSTON ABRAHAM, the author of 'The Surgeon's Log,' a very delightful book of travel, is an Irishman, or at any rate was educated in Ireland, and we are sure he will not mind our frivolity when we say that in *The Night Nurse* (London Chapman and Hall, Limited 1913 Pp 311 Price 6*s*) his latest book, he reminds us of Gilbert's Lord Chancellor, whose occupation consisted in "giving agreeable girls away" Yet Dr Abraham writes with the proper element of tragedy mingled with comedy The purely professional portions of the book are exceedingly well done, and the story ranges from grave to gay, in a manner characteristic of the land where the scene is laid ——A thrilling story with a strong psychological interest is *The Blue Wall* by RICHARD WASHUM CHILD (London Constable and Co, Limited 1912 Pp 378 Price 6*s* net) It contains a study of a successful struggle against the morphine habit written by the heroine during her voluntary solitary confinement, which is very accurate and graphic The rest of the book, however, is a jumble of psychology, genetics, and occultism with no particular scientific interest ——The author of *The Triuneverse. a Scientific Romance* (London C Knight and Co 1962 (*sic*) Pp 221) does not reveal his identity further than by describing himself as the author of 'Space and Spirit" Whoever he is, he has considerable acquaintance with physical science and the gift of clear exposition so far as the subject admits of it There is a slender framework of story, the object being to set forth a theory of the structure of the "Triuneverse' made up of a physical series that forms a multiverse which merges into an organic series forming an organiverse, this in turn developing into a spirituverse The whole forms the triuneverse, and that 'to the height of this great argument" the anonymous author (the average reader can certainly not follow him there) successfully attains is perhaps doubtful

Microscopy is now such a large and important subject that a small book dealing with the matter is hardly likely to appeal to medical men, nevertheless they may often be asked by friends to recommend a simple book on the microscope, and they may be glad to know of *The Beginner's Guide to the Microscope*, by CHARLES E HEATH, F R M S (London Percival Marshall and Co 1912 Pp 119 Price 1*s* net) which gives all the information that the novice is likely to require in his early investigations With this book, and perhaps one dealing with objects for the microscope the amateur will be sufficiently equipped as regards literature until the attractions of his hobby make him require more advanced treatises, of which there is a useful list at the end of the book under notice

JOURNALS AND MAGAZINES

The Journal of Physiology Edited by J N LANGLEY, Sc D, F R S Vol XLVI, No 1, March London C F Clay Cambridge University Press Pp 80 Price 5*s* —G R Mines has a paper on Summation of Contractions He used the intramuscular nerves of the sartorius with finely graded stimuli the heart of frog and torpedo From his experiments he concludes that liberation of acid in the muscle as a result of excitation precedes the act of shortening and possibly causes it His other conclusions are formulated in the text —A V Hill contributes a highly technical paper on the Energy Degraged in the Recovery Processes of Stimu*lated Muscles, which is a continuation of a paper published* in 1911 By means of a new thermo electrical apparatus the rise of temperature of a muscle may be estimated to within a millionth of a degree In a muscle excited in oxygen the production of heat is continued for long periods after the mechanical response is over In a muscle left in nitrogen there is no trace of heat production after the contraction is over, but if it be transferred to oxygen the same amount of heat production as is normal occurs after the contraction is over It is suggested that the processes of muscular contraction are due to liberation of lactic acid from some precursor and that oxygen in all living tissues is used largely in the oxidations, whereby the molecular machine, like a steam engine charging an accumulator, builds up bodies containing considerable amounts of free energy, which as in the accumulator, can be discharged whenever desired on subjecting the tissues to appropriate stimuli

L'Hygiène March, 1913 (Messrs Goupil and Co, 25, Bedford street London)—The current issue of this interesting and well illustrated review contains two articles of particular interest at the present moment The first is L'Hygiène du Soldat, by Dr Horace Bianchon which is concluded in this number At the present moment when five nations in Europe are still under arms, and six others are placed in such relations to each other and to the belligerents that, remote as the probability may now be, it is possible that they too should be involved, the question of the health of the soldier is of the greatest possible importance Dr Bianchon describes the responsibilities of the medical officer of the regiment very well, pointing out that he has to be an all-round man if he is to give satisfaction and to feel that he is discharging his responsibilities. He must, for example, be able to satisfy the military authorities as to the absolute necessity of certain soldiers being placed on the sick-list, and he must at the same time be able to "dépister les ruses," by which many malingerers will attempt to avoid the discharge of their duties. This means that he must be a good diagnostician; also he must be rapid in his decisions, a skilful surgeon, and an able administrator. Dr. Bianchon's article is not written with regard to the duties of the military surgeon in times of war, he is discussing the methods of maintaining the health of the soldier while with the colours; but it follows that the more perfect the administration of the medical service of a nation is in times of peace the more effective will the army be as a fighting machine. For first, the number of healthy men in the army will be larger if hygienic precautions are duly taken; and secondly, the routine for coping with the pathological results of war—disease as well as injury—will only operate satisfactorily under stress if it can be tested with deliberation. The other article in this issue of *L'Hygiène* which calls for notice is a symposium on the subject of depopulation, in which are collected the opinions of Dr. Löwenthal, the late Professor Lannelongue, Dr. Bertillon, Dr. E. Labat, M. Klotz (the French Minister of Finance), Professor Hayem, Professor Pinard, M. Paul Strauss, Professor Chantemesse, Dr. Jacquet, and lastly M. Gustave Mesureur, Director of the Assistance Publique in Paris. The general conclusions which are come to by M. Henri Meurisse as a result of the interesting evidence which he has got together are:—(1) that the depopulation in France, which has become critical, is the consequence of the social conditions, the improvement of the lot of the individual conducing to the diminution of the race; and (2) that, serious as the matter is, the remedy lies not in improving the public health so much as in the alteration of public manners. Is it possible, the conclusions ask, for some legal enactments to restore to the French nation *la goût de famille?* The various opinions of the able men which have been collected in this essay will be read with great interest, but we do not quite see in what direction the law can help other than by combating alcoholism, tuberculosis, syphilis, criminal abortion, and, where possible, the various causes of infantile mortality. Such legislation, however, is made to insure the promotion of public hygiene, and can only in an indirect way be considered to promote and encourage domesticity. In short, the reasons for desiring a logical plan upon which to fight a growing danger are set out in this symposium, but the terms of such a plan are only barely suggested.

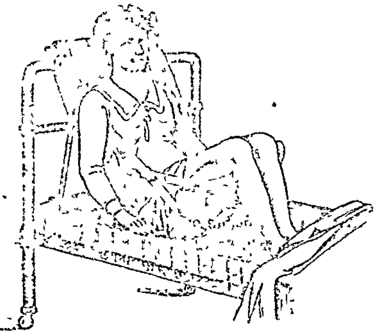
Quarterly Journal of Experimental Physiology. Editors: E. A. Schäfer, F. Gotch, W. D. Halliburton, C. S. Sherrington, E. H. Starling, and A. D. Waller. Vol. VI., No. 1. London: Charles Griffin and Co., Limited. Pp. 108. Price 7*s.* 6*d.*—W. Cramer and Harold Pringle record their experiments on the Coagulation of Blood. They find that oxalate plasma, when filtered through a Berkefeld filter, does not clot on the addition of calcium chloride. Some of the phenomena which have been attributed to the chemical or physical properties of the unorganised constituents of the plasma are in reality due to behaviour of the living cellular elements, and amongst these the platelets play a most important rôle.—W. Gavin finds that the administration of extracts of pituitary body and corpus luteum to dairy cows, by the mouth or by subcutaneous or intravenous injection, causes practically no alteration in the total quantity per diem or in the quality of the milk.—E. A. Schäfer records the effect of pituitary and corpus luteum extracts on the mammary gland in a young married subject nursing her second baby. There is ample evidence of the positive effect of these extracts, especially as regards the pituitary extract. It is desirable that more observations of this nature should be made.—C. M. Gruber finds that natural and artificially aroused impulses in the phrenic nerve, which is a mixed nerve containing both afferent and efferent fibres, can be arrested by an electrical, block, and by freezing mixtures, especially by liquid air.—T. Graham Brown continues his elaborate researches on the Physiology of the Nervous System, and in this (the twelfth) contribution deals with Rhythmic Responses in the Simple Reflex—Progression—Scratch.—F. R. Miller records his results on Reactions of the Salivary Centres. Stimulation of the central end of the lingual nerve—lingualis reflex—amongst other effects causes abundant secretion from the ipsilateral submaxillary gland. Similar stimulation of the glosso-pharyngeal nerve causes similar results in the parotid of the same side, while stimulation of the central end of the vagus—gastric vagus reflex—causes secretion from the submaxillary and parotid glands, but the threshold is high. The salivary reflexes are independent of the associated muscular reflexes. The chorda tympani contains afferent fibres for the salivary reflex. The salivary secretion of curare poisoning is caused by asphyxia. In the bulb two points can be localised: stimulation of the one causes parotid secretion, of the other submaxillary secretion.—P. T. Hering contributes Further Observations upon the Comparative Anatomy and Physiology of the Pituitary Body of Cyclostomes (lamprey and myxine), Elasmobranchs (skate), Teleosts (cod), Amphibians (toad and frog), Reptiles (tortoise and green lizard), and Birds (fowl, starling, and thrush). From his observations the author concludes that the presence of active physiological principles in the pituitary body is associated with a tissue of nervous origin—the pars nervosa. There is reason to believe that the granules therein contained are representatives of the active principles, and that they are products of part of the epithelial lobe—pars intermedia—carried to, elaborated in, and stored by, the pars nervosa.

Jahreskurse für ärztliche Fortbildung. February, 1913. Munich: Lehmann. Price 18 marks per annum.—The February number is devoted to a review of recent work in relation to diseases of the heart and lungs. Professor Hoffmann, of Düsseldorf, writes on irregularity of the heart beat. The methods of study in clinical work are auscultation, palpation, the sphygmograph, sphygmocardiochronograph, and electrocardiogram. The work of Mackenzie and Lewis is described in some detail. According to Engelmann, the nervous control of the heart influences it both positively and negatively in four different directions, the rate (chronotropic), the response to stimulus (bathmotropic), the conductivity (dromotropic), and the contractile power (inotropic). The various forms of cardiac irregularity are classified under the headings of sinus arrhythmia, including the juvenile respiratory arrhythmia and the tachycardias; the ectopic arrhythmias, including extrasystoles and extrasystolic tachycardia (heart galloping); the various forms of heart-block, absolute irregularity, and pulsus alternans; sphygmograms and electrocardiograms are given illustrative of these conditions. The treatment is briefly discussed, and also the prognostic import.—Velden contributes an article on the physical diagnosis of heart affections, and the significance of variations in the size, motility in the chest, and the heart sounds.—Stähelin, after a brief dissertation on the relations between the lungs and the circulation, discusses treatment by means of the various tuberculins. He passes in review Koch's old tuberculin, describing how it is used in diagnosis. For treatment, doses of 1/10 mg. twice weekly are recommended; but if this causes fever 1/100 or even 1/1000 mg. may be used. It is most useful for early apyrexial cases, but may be used also in the presence of fever. New tuberculin (T.R.), bacillary emulsion, Denys' tuberculin, and Beraneck's tuberculin are then described. The last, prepared by Beraneck, in Neuchâtel, contains an albumose-free bouillon culture extracted with phosphoric acid. It is put up in various dilutions, one recommended for treatment being A/64 in 1/20 c.c. doses (Sahli), increased if no reaction appears up to ½ c.c. Rosenbach's and Landmann's tuberculins are also mentioned. Opinion differs widely as to which of these is the best, and some think that they all contain the same active principles. Tuberculin ought not to be used when there exists a generalised tuberculosis, diabetes, or other systemic disease.

New Inventions.

PILLOW AND STRAPS FOR MAINTAINING THE "FOWLER POSITION."

THE comfort of these straps to both patient and nurse has been demonstrated by a trial extending over three years. The pillow is 2 feet in length and 1 foot in width, is stuffed firmly, and is covered with mackintosh. In the centre of one side a semicircle is cut. Two webbing straps are attached to one face of the pillow in its long axis, the adjacent ends of these straps converging to terminate in a buckle at each end of the pillow. Two separate straps, having at one end a leather loop, connect at this end with the head rail of the bed, and at the other end with the buckles on the pillow. The pillow and straps are devised for maintaining, not for dragging the patient into the Fowler position. The method of use is for the patient to be supported, at the required angle, on a bed rest. The two loose straps are looped to the top rail at the head of the bed about 2 feet apart. If the head rail of the bed is on a lower level than the shoulders of the patient, the straps must pass from the bed rail up over the top of the bed rest and then under or outside the patient's arms down to meet the buckles. The pillow with its straps below—i.e., next the bed—and the edge with the semicircular gap upwards (next the rectum) is covered with a warmed towel and slid across the bed beneath the thighs reaching up to the buttocks. The ends of the straps from the head of the bed are passed through the buckles of the pillow. *A nurse on each side of the patient, with one hand* under the pillow, first gradually raises the pillow and thighs and then, with the other hand, tightens the straps in the buckles. These straps must be tightened equally until they are quite taut. On removing the hands from beneath the pillow the patient is supported on the seat of a swing, but the seat of the swing—the pillow—rests, not against the buttocks, but against the back of the thighs immediately in front of the buttocks. The soles of the feet are supported on an ordinary pillow. The semicircular opening, lying opposite the perineum, allows access to the urethra and rectum and is especially useful if saline solution is being administered per rectum.



Messrs. Allen and Hanburys, Limited, of Lombard-street, London, E.C., have, at my request, undertaken the manufacture of these straps.

O. HAMILTON WHITEFORD, M.R.C.S. Eng.,

Among the subscriptions from individuals is a donation of 500 marks from Professor Ehrlich and one of £100 from Lord Strathcona.

Committees for the purpose of collecting subscriptions have been formed by the Universities of Oxford, Cambridge, and Durham, and other Universities are also making efforts locally to promote the success of the memorial. Arrangements have also been made for the formation of committees in the British Dominions beyond the Seas and in foreign countries.

The proposed memorial will be of a threefold character, and consist of: (1) a simple marble medallion bearing a sculptured portrait of Lord Lister to be placed in Westminster Abbey among the monuments of the nation's illustrious dead; (2) a larger and more conspicuous monument to be erected in some public place in London; and (3) the founding of an International Memorial Fund from which either grants in aid of researches bearing on surgery or rewards in recognition of important contributions to surgical science will be made, irrespective of nationality. A considerable sum of money is required to carry out these proposals. Donations should be sent to the Treasurers of the Fund, at the Royal Society, Burlington House, London, W.

THE LATE DR. EDWARD ADRIAN WILSON.—March 27th being approximately the anniversary of the death of Captain Scott and his companions on the return from the South Pole [illegible] in the chapel of [illegible] Wilson, an [illegible] field, in the [illegible] Dr. Wilson had hoped on his return from the South Pole to *enter the ministry of the Church*. The canon also quoted a letter written to a friend by a member of the expedition, in which the writer said: "Words must always fail me when I talk of Wilson. He really is the finest character I have ever met. Every quality is so solid and dependable, sound, shrewdly practical, intensely loyal, and utterly unselfish. He is the most popular member of our party."

THE LANCET.

LONDON: SATURDAY, APRIL 12, 1913.

The Care of the Mentally Deficient.

IN fulfilment of the promise made on behalf of the Government when the withdrawal of the Mental Deficiency Bill was announced last year, the Home Secretary has introduced into the House of Commons a measure on similar lines, which, so far as the Parliamentary omens of the moment will allow of a forecast, seems likely to pass into law during the present session. There is the more reason to entertain this hope in that the provisions of the new Bill, a comprehensive abstract of which appears elsewhere in our columns, are in some respects more limited in their scope, and therefore less likely to arouse prejudice and afford opportunity for misunderstanding and misrepresentation than were Mr. MCKENNA's original proposals. It will certainly not be a matter of regret to those who most keenly realise the gravity of this problem, if it has been found possible, without the sacrifice of any essential principle, to meet criticism which had its source—and this was undoubtedly the case with much, at all events, of the opposition to the abortive measure of last session—in a genuine and conscientious, if quite groundless, fear lest measures for the control of the feeble-minded should be abused and perverted to the violation of the rights of the individual citizen. The safeguards provided in the present Bill should satisfy even the most exacting critic that any risk of this sort is entirely illusory. What is perhaps more to be feared is that these elaborate precautions against abuse may be found in practice to hamper so largely the operation of the measure as to curtail to some extent its utility and to deter judicial authorities from applying its provisions in face of ignorant or interested opposition. It may be hoped, however, that public opinion on this question, which has developed so remarkably within the last few years, will be strong enough to cope with this difficulty should it prove serious.

The Bill now before Parliament, though embodying the same general principles as last year's measure, differs very widely from it in some details of considerable importance. Apart from the greater limitation of its scope, to which reference has already been made, the most notable of these differences is in respect of the central authority for the administration of the proposed Act. In accordance with the amendment adopted when the matter was discussed in Committee last session the present Bill entrusts this duty to the Lunacy Commissioners, the constitution of that body being modified, its numbers increased, and its title changed to that of the Board of Control. It is provided that a certain number of the members of the Board, including all the medical members, shall be appointed by the Home Secretary, while the legal representatives are to be nominated, as heretofore, by the Lord Chancellor. This arrangement, which establishes a single central authority for the care and control of the insane and the feeble-minded, and which brings that authority into intimate relation with the Home Office, appears to be acceptable on grounds alike of logical propriety and of practical convenience. It should meet the views of those who recognise the importance of assimilating the treatment of the feeble-minded to that of the insane, while at the same time it will, no doubt, secure for the guidance of the new administrative body the valuable experience acquired by the Departments of the Home Office which have had to deal for many years with criminal defectives and inebriates. And as these latter categories of the mentally deficient will probably be amongst the first to be brought under the operation of the Act, their transfer to the jurisdiction of the new authority will now be a much simpler process, and will be attended with much less risk of friction than would probably have been the case had the administration of the Act been entrusted to a totally distinct board, independent of and unconnected with the Home Office. Moreover, it may be expected that the incorporation of the Lunacy Commissioners under their new style in this department of the Government will have indirect results of an important and beneficial character by bringing the influence of alienist opinion into effective contact with those other branches of Home Office administration, which in prisons, in reformatories, and in inebriate institutions have to deal with populations so largely recruited from the ranks of the degenerate and the mentally abnormal. The advantages that should accrue to the work of these departments from a fuller recognition of the point of view and the methods of psychiatry are too obvious to need more precise indication. For these various reasons, then, the proposals in the new Bill with regard to the central authority appear to be preferable to the scheme originally put forward; they utilise the existing machinery, while at the same time they facilitate its modification so far as may be found necessary to adjust it to the new functions which it will have to fulfil. Another important point in which the present Bill shows an improvement on its predecessor is with respect to the definition of mental deficiency. The difficulty of framing a definition, scientifically accurate, and also suitable for adoption in an Act of Parliament, is quite as formidable in the case of feeble-mindedness as it has notoriously proved to be in the case of insanity; and the attempt made in last year's Bill to construct a fitting formula for the purpose was hardly attended with such success as would encourage further effort in this direction. The difficulty is met to some extent in the present Bill by including in the definition clause a specific reference to the several categories of defective persons who are liable to be dealt with under the compulsory powers of the Act, as, for instance, defective persons who become amenable to the ordinary criminal law or to the special legislation for inebriates. In this connexion it may also be noted that occasion has been taken to repair a rather remarkable omission in the former Bill by adding a clause requiring that there must be a *medical* examination before an order is made under the Act.

While the provisions of the Bill may, in a general view, be regarded as sound and well-considered, it may be questioned whether the administrative machinery which it proposes to set up will prove to be adequate to the amount and complexity of the work that it will have to do. This doubt will be felt more particularly with regard to the medical representation on the Board of Control, which, as the Bill stands at present, is left at the same strength as on the existing Lunacy Commission. It is, however, notorious that the number of medical Commissioners in Lunacy is even now absurdly insufficient for the heavy and responsible duties which they are required to perform in the supervision of the certified insane; and it is barely reasonable to expect that these hardly worked officials are to find additional time in which to organise and carry out the details of a novel, and to some extent an experimental, policy. And these considerations will appear still more cogent when it is borne in mind that the duties which will devolve on the Board of Control in connexion with the feeble-minded will not be simply duties of supervision and inspection, as are in a great measure the duties of the Commissioners under the Lunacy Acts. The provisions of the Mental Deficiency Bill already indicate that the central authority will have to deal regularly with questions as to the propriety of discharge or continued detention in the case of individual defectives—that is to say, with what are virtually questions of diagnosis; and it is safe to predict that this tendency will become stronger as time goes on. For mental defect, unlike acquired insanity, is by its nature a permanent condition, and it is a condition, moreover, which lacks those distinctive symptoms that furnish the ordinary data for certification. On account of these two characteristics the procedure in the case of the defective cannot be the same as in the case of the lunatic. Hence it may be foreseen that, for the avoidance of the confusion which would inevitably result from personal and local divergences of practice, it will very soon be found necessary to establish definite criteria by which the existence and degree of defect may be ascertained, and any such system will presumably imply the intervention of a central authority with expert knowledge, which would naturally be provided by the medical element on the Board of Control. Though such an evolution may not be contemplated by the framers of the present Bill, its probability will be obvious enough to those who have had practical experience in dealing with the feeble-minded; and it might be preferable that provision should be made for this development at the outset, instead of waiting for conflicts of doctrinal opinion and disputes as to procedure.

The Milk and Dairies Bill.

IT is almost superfluous at this date to recall the grounds on which legislation is required to secure a purer milk-supply in this country. The exact proportion of the milch cows in England which are tuberculous cannot be accurately stated, but if it were only one in a hundred, which is certainly an underestimate, it represents a danger of the first magnitude to a host of children, and probably to a not inconsiderable number of adults also. Not a year passes without evidence, from the investigations made by medical officers of health and bacteriologists, of outbreaks of other infectious diseases, such as scarlet fever, enteric fever, and the sore throat associated with mastitis of the cow, which have been caused by the infection of the original milk or its subsequent contamination. The domestic boiling of milk, which would destroy the bacilli of these diseases, has been advocated by sanitarians for half a century, but the fact must be faced that few people will do it, and the nation as a whole is not likely to abandon its preference for milk in the uncooked state. If a census could be taken of the households of medical men in the country—or even of medical officers of health alone—we should be surprised if habitual boiling of milk was found to be the rule and not the exception. The proposal that all milk before delivery to the consumer should be required by law to be pasteurised is open to several serious objections, while it would be almost impossible to check the efficiency of the processes adopted. The supply of milk, therefore, must in the public interest be protected from specific infections, and ought also to be safeguarded against the great variety of potentially dangerous contaminations which it so often receives in the course of its journey from the cow to the customer. There are few sanitary matters of which this country has so little cause to be proud as the methods which are so commonly adopted in the storage and conveyance of milk. Only indifference resulting from long familiarity with bad habits can explain the continuance of the entirely unnecessary dirt contamination which is so often witnessed when milk churns are conveyed by rail or taken through the streets on the milk round; and here also the result is shown in a toll of infant life, particularly from epidemic diarrhœa. Further, it is well known that much systematic sophistication of milk takes place, favoured by the ease with which penalties can be evaded by the defence of "warranties," and that in this way a widespread impoverishment of this most important part of the food of the people is brought about.

It is now universally acknowledged that the various Acts and Regulations under which impurities and infections of milk can be controlled are inadequate in themselves and are very unequally administered, and that in this respect the provisions of the several Public Health Acts, the Infectious Disease Prevention Act, and the old Contagious Diseases of Animals Acts, need to be revised, strengthened, and consolidated in a single enactment. This reform, which is demanded on behalf of the public by those authorities who at present are responsible, has also been strongly urged of late years by the more far-seeing section of the milk industry. The Government have long been understood to be pledged to new legislation; but it is unfortunately true that for some years past their performance in the matter has been regrettably feeble. The situation seemed changed for the better towards the end of the last session of Parliament, when Mr. JOHN BURNS introduced a new Milk and Dairies Bill, apparently with the object of making its provisions known in advance, so that real progress could be made with it in the present session. This Bill, which we discussed and welcomed in our issue of Dec. 21st last, has now again been formally introduced, and we trust that Mr. BURNS will not omit any effort to secure its passage, and thus remove what has threatened to become a standing reproach to the central public health department over which he presides. The Bill in its main lines seems to have met with approval, though some of its clauses have received considerable criticism from medical officers of health and the different local authorities which will be concerned in giving it effect. The principle of relegating to future departmental regulations important matters such as the control over the sanitary arrangements of cowsheds and the cleanliness of milking, the system of registration of dairies (which in the Bill include not only dairy farms and cow-byres, but also milk shops and other premises where milk is obtained or stored), and the details of their inspection, has, we are glad to note, received general acceptance. Departmental regulations can be varied if they are found unsatisfactory in experience, and no new measures of reform in connexion with such a complex and important industry as the milk trade can be so perfect as not to call for fairly frequent adjustments in practice. The principal objections which have been urged to the Bill relate to the choice of the executive authorities that has been made. The Bill places most of the administrative duties on district councils and county councils concurrently, the latter authority having supervisory powers, but in "rural" districts the county council is to act to the exclusion of the district council for certain purposes, such as making investigations into complaints that infectious disease has been caused by milk sent out of the district, and making orders to stop the sale of infected milk. County medical officers of health, if we may judge by a recent contribution to *Public Health* by Dr. W. G. SAVAGE, see many difficulties in taking responsibility in a sort of patchwork over their counties. On the other hand, whole-time district medical officers of health, especially those who act for combined areas, have pointed out that they could themselves exercise the necessary supervision and control more efficiently than is practicable at a county centre. This contention has been forcibly expressed in the case of the eastern portions of Surrey by Dr. A. E. PORTER in his annual report for the Reigate district. It must be realised, however, that when the new Order of the Board of Agriculture relating to the slaughter of tuberculous cattle, with a view to compensation, has taken effect next month a strong reason will be furnished for control being exercised in health matters by the same authorities which carry out the veterinary work.

Criticism has also been expressed of the proposed repeal of the "milk clauses" in several local Acts which gave the health authorities power to trace infected milk back to the farm in the country and stop its supply to the city. It has been contended that these powers should remain at any rate for a few years after the passing of the Act, until these cities are satisfied that the county supervision is adequate. At a recent discussion at the Royal Sanitary Institute Mr. HERBERT JONES drew attention to the invidious position in which medical officers of health may be placed in carrying out their duties under the Bill, and it is suggested that clauses should be added to provide for security of tenure of district medical officers of health, analogous to those relating to county officers which were introduced a few years ago into the Housing and Town Planning Act. We trust that the Bill will be given its second reading as soon as possible, so that these and similar matters of administrative detail may be fully dealt with in committee. As we before have pointed out, it is in favour of the prospects of the Bill that in several points it already represents a working compromise between the more extreme demands of public health administration and the opposition which was at first made in the interests of the milk industry, and critics on both sides may now do well to remember that the best is sometimes the enemy of the good.

Unexpected Recoveries from Insanity.

THE cases which Dr. LEWIS C. BRUCE, of Murthly Asylum, records in another column of THE LANCET present features to which it may be well to direct attention. In one case a confirmed epileptic of many years' standing was apparently cured—in so far as an interval of eight years of freedom from seizures may be said to constitute a "cure"—by the withdrawal of 40 c.c. of blood from the median basilic vein once a week for six consecutive weeks. In the second case, a patient with cyclical insanity of manic-depressive type, it was discovered that her blood contained a specific agglutinin to a variety of streptococcus obtained by Dr. BRUCE from the blood of another patient who suffered from acute mania. By feeding the former on living cultures of this streptococcus a striking improvement set in, and whereas prior to the date of treatment—October, 1905—her attacks of insanity occurred every year, and sometimes frequently in the year, from that time to the present there has been no relapse. A third case is that of a patient with what appeared to be chronic delusional insanity, who contracted scarlet fever, and in whom convalescence from the fever was accompanied by complete disappearance of the delusional symptoms. For three years she has been quite well. The fourth case is that of a patient with delusions of identity, a morose, impulsive, absolutely intractable woman, to quote Dr. BRUCE'S own words, who after four years of this condition suddenly became unconscious one day, developed a right hemiplegia with aphasia, followed by high irregular fever, and when, some five weeks later, she had recovered to a great extent from the effects of the "stroke," it was found that her mental condition was entirely normal, apart from a complete retrograde amnesia for the events of the preceding four years. She was discharged recovered, went into service, and has apparently kept in good health since—i.e., for almost five years.

Each of these four cases presents points of interest, and three of them have this in common, that an alteration in the psychical state was effected through the agency of another form of disease. The case of recovery of a maniacal patient after being fed by streptococci presents difficulties; the technique here must be above reproach, and other experiments with every precaution against error would be advisable before any conclusions are drawn from it. Further, it is possible that in the last case narrated the intercurrent disease was not cerebral hæmorrhage, as Dr. BRUCE is inclined to think, but encephalitis; in other words, a toxi-infective condition. The fever, which was one of the notable symptoms, is in favour of such a diagnosis, while the age of the patient (27) is somewhat against the likelihood of hæmorrhage. However, be this as it may, the case is of great interest. It is fairly well recognised that the incidence of an intercurrent affection may have a curiously ameliorating action on the course of a pre-existing disease, and instances will no doubt occur to the reader. We know of a patient suffering from a well-established delusional insanity who, in suicidal mood, threw herself out of a window, sustained a fracture-dislocation of the lumbar vertebræ, and from that date her mental symptoms vanished and have not returned. It is difficult to appreciate the real meaning of such a course of events; the difficulty is not, perhaps, so great in cases where the morbid process that supervenes is definitely toxic or toxi-infective, as in various recorded examples, and in one or two of those given by Dr. BRUCE. Nor need there be any insuperable difficulty in explaining the interesting amnesia of the fourth case of Dr. BRUCE, for if an ictus, such as a blow on the head, can occasion a retrograde amnesia, there seems to be no valid reason why the ictus of a sudden hæmorrhage or encephalitis should not be capable of producing a similar result in a particular case. We have heard of an old gentleman noted for his devoutness and religious nature who, ever since an attack of right hemiplegia without aphasia, has had the greatest difficulty in retaining or expressing his conceptions of the Deity, and admits that to his distress he seems to be unable to recall the familiar truths of his religion.

It is well that the profession should hear of such instances as Dr. BRUCE records, for they serve to show how alterations in what were once thought the intangible and inaccessible realms of the insane mind can be brought about by definite encephalic processes. We cannot agree with those who would limit the possibilities of cerebral localisation; after all, if a cerebral tumour can effect changes in a man's disposition, character, and temperament, then these features of his psychical "make-up"—to employ a useful if colloquial Americanism—must have some anatomical substratum, and we welcome all evidence that will aid in the elucidation of the interrelations of the two. To lay too great stress on scanty data would be injudicious; nevertheless, it is equally a mistake to ignore them Dr. BRUCE'S cases further illustrate the startling nature of some recoveries from a condition of insanity—recoveries not merely unexpected, but previously regarded as quite improbable. And the same may be said for the remarkable recovery described in a letter this week by Dr. J. BATTY TUKE. Such cases indicate, it must be confessed, our comparative ignorance of the nature of not a few pathological mental states, but their suggestiveness will be noted by the alienist and physician.

ROYAL INSTITUTION. — On Tuesday next (April 15th) at 3 o'clock, Professor W. Bateson delivers the first of two lectures at the Royal Institution on the Heredity of Sex and Some Cognate Problems, in continuation of those delivered before Easter. The Friday evening discourse on April 18th will be delivered by Dr. T. M. Lowry on Applications of Polarised Light; and on May 2nd by Mr. H. G. Plimmer on Blood Parasites.

Annotations.

"Ne quid nimis."

THE CONTROL OF PETROL.

IN 1908 *a Departmental Committee was appointed to* inquire into the sufficiency of the existing regulations relating to the storage, use, and conveyance of petroleum spirit, and to report what further precautions, if any, were in their opinion desirable as tending to diminish the dangers attendant thereon. In 1910 the committee presented their first report, but certain evidence was not forthcoming; this, however, has since been obtained, and has enabled them to present their final report which was issued last week. In this report provisions are recommended in regard to the conveyance of petroleum spirit by road, and further powers, it is suggested, are to be conferred upon harbour authorities in connexion with making by-laws under the Petroleum Acts. It is also recommended that, generally speaking, the provisions of existing Acts—to wit, the Petroleum Act of 1871 and the Explosives Act of 1875—should be more strictly enforced by local authorities. In regard to the conveyance of petroleum spirit in the river Thames, in particular (to the dangers of which considerable attention has been drawn), the committee uphold the views of the Port of London Authority that tank steamers shall not be allowed above Thameshaven, although they have decided to allow greater facilities for the conveyance of petroleum spirit up the river in licensed tank barges, by increasing the capacity of the barges and by allowing self-propelled barges having engines of a certain type. Recommendations are also made with respect to the safe storage of petroleum for trade purposes and to the domestic use of petrol. The use of petroleum spirit hair-washes in hairdressing establishments should, in the opinion of the committee, be prohibited, and it should be made illegal, they add, to use petroleum spirit or mixtures containing it "on the hair of the living subject." It should be made illegal, they also think, to allow any petroleum spirit to escape into any inlet or drain communicating with a sewer. As regards the keeping of petroleum spirit for use in motor vehicles, no great change appears to the committee to be necessary. It is suggested, however, that a certain regulation should be amended allowing of two spare tins being carried on a motor-car without notification to the local authority, and that a regulation should be added making it compulsory to keep a supply of dry sand or some suitable substitute in every storehouse or garage. As a whole, the report seems to present useful, temperate suggestions, inflicting no hardships, while at the same time offering better protection both of person and property from a highly inflammable material, the increasing use of which is a feature of modern times.

MEDICAL EXAMINATIONS IN SWITZERLAND.

THE regulations for the Swiss medical examinations of 1877 and 1886 have been completely revised. The new regulations, dated Nov. 29th, 1912, come into force for the first time this spring. The examinations still take place at the principal university towns—Basel, Berne, Geneva, Lausanne, and Zürich—and are conducted in German or French (Lausanne and Geneva) (The innovations in the new regulations are marked in italics.) Only persons who have passed the Swiss Matriculation Examination are admitted to the three medical examinations—first, second, and final. The successful passing of the final examination provides the candidate with a Swiss Federal diploma and admits him to practise in any canton of Switzerland. The M.D. examination is separate, and has solely an academical or scientific value. The first medical examination is oral and deals with four subjects—viz., physics, organic and inorganic chemistry, botany, and zoology. (*Foreigners with recognised diplomas can be exempted from this examination.*) The subjects of the second examination are anatomy, histology, embryology, and physiology, and it is partly practical (dissection), partly oral, and partly written. Admission to the final examination is granted after 11 half-yearly terms of study, six of which must be spent in Switzerland. One-half year's attendance at a recognised hospital can replace one-half yearly term of study. The candidate must give proof of having attended the medical, surgical, and obstetric cliniques for two terms; the *children's* and ophthalmological *cliniques*, the medical and surgical out-patient department, the mental hospital, and the *oto-laryngeal clinique* for one term. The candidate, in addition, must pass practical and theoretical examinations, the latter both oral and written, in the following subjects: pathological anatomy, internal medicine, surgery, obstetrics and gynæcology, ophthalmology, *pædiatrics*, *dermatology and neurology*, mental diseases, hygiene and *legal medicine*. There is also an oral examination in the *surgery of accidents* (*Unfallkunde*) and materia medica. For written examinations four hours are allowed; the spoken examinations generally last half an hour for each candidate.

MARCH AT HOME AND ABROAD.

MARCH lived up to its reputation for boisterous winds. Gales on various parts of the coast were very frequent, and sometimes unusually severe, while high squally winds and even gales were not uncommon over inland districts. The main direction of the wind, however, was from some point of the compass between south and west, and the atmosphere was consequently less dry than during the proverbial March, and the temperature rather high. There were, nevertheless, no very warm days such as sometimes occur during a March with a much lower mean temperature. Maximum readings above 55° were seldom experienced even in the warmest portions of the kingdom, although the thermometer mounted to between 50° and that figure on the majority of days. Night frosts were few and rarely severe; in the Midlands and North of England there were only about eight occasions when the screened thermometer descended below 32°. At the Kew Observatory frost was recorded on six nights, the lowest temperature being 28°, but the mean minimum for the month was no lower than 37°, or 1·5° above the normal. On 20 afternoons the maximum temperature was above 50°, and the mean value 51°, or rather more than 2° above the normal. Ordinarily March is one of the driest months of the year, but with the prevailing wind current in the south-west the period under review was an exception. At Kew, where a normal March gives rain on 13 days, more or less rain fell on as many as 20. There were, however, no very heavy downpours, and the aggregate fall of 2·14 in. only exceeded the average by 0·55 in. A very bright day was as rare as a dry one, and the total duration of sunshine fell short of the normal. At Kew, where the average for March is 109 hours, there were no more than 87 hours, and on no less than 12 days there was either none or less than an hour. The greater part of the midlands and north was appreciably colder than London, as well as more rainy, but not everywhere so dull. At Nottingham the mean minimum was only a trifle lower, but the mean maximum was 1·5° lower; and the total rainfall, which fell on as many as 22 days, yielded 3·42 in., exceeding the average by 1·83 in. In spite of the many rainy days, however, the sunshine at Nottingham was five hours more than at Kew. At Bath the mean maximum temperature was a fraction of a degree higher than at Kew, but the mean minimum was more than 1° lower. As at Nottingham, there were 22 days with rain, and the total fall of 3·42 in. exceeded the average by 1·37 in. The sunshine record was 21 hours less than usual, but the total of 98 hours was better than that of Kew. In the extreme south-west of England the weather was more rainy than in the south-east, but also brighter. Newquay had 23 days with rain and the large total of 4·67 in., while the sun shone for as many as 121 hours, exceeding the Kew total by more than an hour per day. The temperature at Newquay was far more equable than at places in the east and centre. The mean maximum, 50°, was only 10° higher than the mean minimum, while further west still, at the Scilly Isles, the corresponding figures were 51·3° and 42·0°. At Scilly there was considerably less rain than on the nearest parts of the coast, but more cloud, the aggregate sunshine amounting to 113 hours—eight hours less than at Newquay. Practically all parts of the Continent were much drier than this country. At Paris rain fell on 10 days only, giving a total of 1·66 in. The French capital was also warmer both at night and during the day than Kew, having a mean maximum temperature as high as 55°, and a mean minimum no lower than 38°. There were, however, in spite of the few rainy days, many more cloudy ones than is general in March. The total sunshine, 97 hours, was only ten hours more than at Kew, and many hours less than on the south-west and south coast of England. At Berlin rain fell on ten days, yielding a total no higher than 1·38 in., while the temperature, at first low, subsequently increased very decidedly, until at the end of the month it touched a maximum as high as 73°, a figure several degrees higher than any recorded at Paris, Biarritz, and Nice. The mean of the maxima, 52°, was not very high, and the mean minimum, 36°, was lower than at Kew. On the Riviera the greater part of the month was bright and dry, but some heavy rain fell during the latter half. At Nice the temperature seldom fell below 40° at night, and occasionally rose to above 60° during the day. The mean maximum equalled 58° and the mean minimum 43·5°. In the south-western corner of France, as represented by Biarritz, the temperature was more variable. Slight frost occurred on the 9th, while maximum readings above 60° were more numerous than at Nice. The mean of the maxima was as high as 59° and the mean of the minima 43·3°. Like Paris and Berlin, rain fell on ten days only, all during the latter half of the month, and except quite at the end the falls were slight or very moderate. At Madeira there was rain on only one day, and even an overcast sky was a rarity. The temperature, both during the day and night, showed a gradual upward movement compared with the previous month. The mean maximum was not far below that of June in London, the figure being 66° and the mean minimum 49°.

ANEURYSM OF THE SUPERFICIAL PALMAR ARCH.

IN the *Revue de Chirurgie* for March M. Jules Regnault and M. Bourrut-Lacouture, of the Naval Medical School, Toulon, have collected a series of records from the literature of aneurysm of the superficial palmar arch, amounting to 26 cases in all; to this they add another from their own experience which presented some interesting features. The patient, a gunner, aged 37, was healthy and free from syphilitic infection. In August, 1910, he was obliged to strike his gun heavily several times with the palm of the hand; this caused sharp but transient pain. Three weeks later a swelling of the size of a pea was noticed in the palm, and tingling sensations developed in the third and fourth fingers. These soon disappeared, so that the swelling ceased to attract much attention, though it increased in size. When he came under the writers' observation in the following May the swelling was as large as a good sized hazel nut, it lay in the upper border of the left hypothenar eminence and pulsated distinctly. When pressed upon it creaked faintly, like snow, and on auscultation a soft bruit was heard. The skin covering it was not discoloured or altered in any way, and there were no discoverable pressure effects. Under local anæsthesia the sac was exposed and removed, the wound healed by first intention, and no trouble followed. Comparing this method with others employed by other surgeons in cases previously reported, M. Regnault and M. Bourrut Lacouture conclude that extirpation is the plan of choice, compression is ineffective in most cases, ligature may fail through the presence of free anastomoses, injection and galvano puncture introduce dangerous elements without promising success and the same may be said of simple incision. Aneurysm of the superficial palmar arch is apparently always traumatic in origin; the artery, though efficiently protected, lies in a region which is exposed to injury. In most cases the trauma has taken the form of an open wound, but in several, as in that under consideration, it was in the nature of a contusion, and constitutes an occupational accident. In one such the patient was a cab-driver, and the development of the aneurysm was ascribed to prolonged irritation by the reins and whip, another patient was an engine driver, whose aneurysm originated in a single heavy blow with the palm of the hand on an obstinate lever. The case recorded by M. Regnault and M. Bourrut Lacouture is therefore important, not only from the clinical, but also from the medico legal point of view.

THE DIFFICULTIES OF PUBLIC HEALTH ADMINISTRATION

SOME striking criticisms of the way in which sanitary matters are dealt with in Ilford are expressed by the medical officer of health of that place in his annual report for 1912. Mr. O. F. Stovin refers in detail to a number of restrictions which the district council has lately placed on his work, and considers them so harassing and to have caused so much friction that he invites the council to agree to asking the Local Government Board to hold a full inquiry by one of its inspectors into the system of sanitary administration of the district. The council, in their turn, appear to have asked the sanction of the Local Government Board to the determination of Mr. Stovin's appointment as medical officer of health, school medical officer, and medical superintendent of the isolation hospital, and it may be anticipated that the whole dispute, which is attracting much local attention, will soon come under official investigation. Mr. Stovin asserts that a continued effort has been made to support the authority of the sanitary inspector against the medical officer of health, both in regard to the control of the subordinate officers and in connexion with drainage matters. Ilford is one of the large urban districts of outer London, with a population now estimated at 83,080, and the number of inhabited houses has increased from 7649 in 1901 to 16,856 in 1911. It is at present the duty of the council's surveyor to supervise the drainage of new buildings, and afterwards all redrainage works come under the public health department. So far as concerns the latter department, Mr. Stovin states that "of 277 houses during the last three years where a drainage nuisance was believed to exist, and a notice had been served to open up the drains for inspection, 277, or 100 per cent., had been found in a defective condition and required redrainage," all these defects having been discovered as a result of complaint or arising out of visits for infectious disease. After this it is not surprising if Mr. Stovin's suggestion that the house drains of the district should be systematically tested has met with opposition from persons interested in house property and building. The matter, however, seems one of more than local importance. Those who have experience of public health work in our large towns are only too familiar with the mischief which has been caused by the faulty construction of houses and house drains in past years when by laws were not in existence or were not observed and are well acquainted with the enormous burdens thrown upon the rates and individuals when the defects have to be put right. If the same kind of construction is being allowed to go on unchecked at the present day in a new district within seven miles of London the facts ought to be known and the cause fully investigated. The further developments of the dispute will be watched with interest.

BISMUTH POISONING

LITTLE information is to be found in the text-books on bismuth poisoning, though cases can be found in medical literature for more than a century. Probably the reason is that the toxic symptoms were supposed to be due to impurities, such as arsenic and lead. In recent years, since the introduction of Beck's method of treating sinuses by the injection of bismuth paste and the use of bismuth in skiagraphy, cases of poisoning have been more numerous. In 1887 Dalché and Villjean showed that pure bismuth salts were toxic. They gave a dog daily 10 grammes of the subnitrate without observing any ill effect, but when the salt was put on a raw surface of any extent intoxication often followed. They then made experiments by subcutaneous injection. A dog was injected with bismuth subnitrate on 12 successive days. It died on the thirteenth day. Five days before death there was noticed on the gums of the anterior molars a brownish violet, glistening serrated line. This line extended and became superficially gangrenous, presenting softened greyish white plaques surrounded by a brownish violet areola. Spots of the same colour appeared in the mucous membrane of the mouth. Dalché and Villjean also observed two cases of bismuth poisoning in man, characterised by a black line and white diphtheritic membranes on the gums and bismuth in the urine. Thus the most striking feature of bismuth poisoning is stomatitis. In advanced stages the teeth fall out. In the *American Journal of the Medical Sciences* for November Dr. L. M. Warfield has reported the following case. A girl, aged 9 years, was admitted into hospital on Sept. 9th, 1911, complaining of a sore mouth. She had suffered from psoas abscess which was twice incised. In November, 1910, about 2 ounces of Beck's subnitrate paste were injected into the sinus, which promptly closed and no paste was ever extruded. Within two weeks a black line was noticed on the margins of the gums. This had persisted, becoming more or less prominent from time to time. In August, 1911, an ulcer formed on the mucous membrane of the right cheek opposite the second molar tooth. Later, the right side of the tongue ulcerated. On examination the child was found well nourished. The breath was very fœtid, the teeth were yellowish and many of them were decayed. On the gum margins of both jaws, both outside and on the inner and outer sides, was a dark, violet-black line about 1.5 mm. in depth which did not quite reach the free border. The teeth were not loosened. Along the whole right edge of the tongue was a violet black discolouration which in its widest part measured 2 cm. In its centre was a white opaque serrated membrane adherent to the underlying tissues. On the buccal surface of the right cheek were two ulcers similar to that on the tongue. A skiagram of the right lumbar region showed a shadow 10 cm. long and 2 to 4 cm. broad. Evidently almost all the bismuth remained. No bismuth, albumin, or casts could be found in the urine. Gradual improvement took place, and on Feb. 19th, 1912, the tongue and cheek were healed and the breath was no longer fœtid, but the line on the gums persisted. A number of similar cases of bismuth poisoning have been recorded, and also about 20 deaths. From the records a typical picture can be drawn which differs from that of lead or mercurial poisoning. There are three forms: (1) benign, in which a violet-black line is the only manifestation; (2) moderately severe, in which there is more or less acute stomatitis, which is succeeded by chronic stomatitis characterised by discolouration of the gum margins and tattooing of the buccal mucosa; (3) a severe form in which ulceration occurs, secondary infection supervenes, and general symptoms, such as fever, hiccough, vomiting, and diarrhœa, occur. The bismuth line resembles the lead line but differs from it in colour. The urine may be blackish, and frequently contains bismuth and occasionally albumin and casts.

ALTERNATING OXALURIA AND PHOSPHATURIA.

IN the March number of the *Bristol Medico-Chirurgical Journal* notes are given of two cases in which a condition of oxaluria alternated with one of phosphaturia. The first is recorded by Professor F. H. Edgeworth, and is that of a man, 26 years of age, who was subject to attacks of renal colic and hæmaturia, the urine containing large numbers of oxalate crystals and being strongly acid in reaction. Under the influence of a milk diet these symptoms subsided, to recur again when a more generous regimen was allowed. A dose of sodium bicarbonate would cut short an attack, but an excess of the alkali was liable to precipitate the onset of the alternate condition of phosphaturia. This was likewise accompanied by some pain along the course of the ureter, though it was of a duller character than that encountered with the oxaluria. The difficulty thus arising was finally solved by the observation that the occurrence of the oxaluria could be prevented by careful and prolonged mastication of the food taken, being apparently due to digestive disturbance and resulting gastric acidity. The second case, reported by Dr. C. W. J. Brasher, was that of a man, aged 46, irregular in his habits, and especially in the matter of eating. He, too, suffered from attacks of lumbar pain and hæmaturia, with painful micturition and some urethritis without the presence of gonococci. Over-exertion and digestive disturbances were responsible for the onset of the condition. These attacks were always followed by phosphaturia, the urine becoming quite milky in appearance. The oxalates present in the urine are usually derived from the food, such articles of diet as rhubarb, strawberries, and spinach giving rise to large quantities of oxalate crystals in the urine, often accompanied by pain and sometimes by hæmaturia. Indeed, the condition may closely simulate renal or vesical calculus. Abnormal conditions of fermentation in the stomach may at times give rise to an endogenous formation of oxalic acid, with a similar urinary condition; but in either case the formation of actual crystals of oxalate of lime as a sediment in the urine depends less on the absolute amount of the salt than on accompanying chemical conditions, such as the acidity of the fluid and the relative proportions of calcium and magnesium salts contained in it. On the other hand, phosphates are only deposited in alkaline urine, a condition which may be produced by large doses of alkalies given as medicine, while milk diet may lead to the presence of much calcium phosphate in the urine. The avoidance of the urinary troubles by the adoption of a habit of prolonged mastication of the food taken may seem to afford some support to the theory that almost all the evils of life may be avoided by this simple procedure, one drawback to the system being, however, that the greater part of the 24 hours of the day has to be devoted to the chewing process if the strict rules are observed.

CARBOLIC ACID IN THE RAILWAY CARRIAGE.

DESIRABLE as it is to keep the railway carriage free from disease germs, there is no reason why the method adopted should leave behind a smell which is suggestive of the fever ward or worse places, and disagreeable to most people. Yet it is the practice of certainly more than one railway company in this country to use a carbolic preparation for the purpose which leaves behind it the persistent odour of the tar acid. It is not conducive to comfort to spend a long journey in an atmosphere which however suggestive of hygiene is also fraught for many with painful associations, and cannot by anyone be considered elegantly perfumed. And there is no reason why the traveller should be subjected to the nuisance, since the disinfecting process can be done in other ways which should give no offence. Possibly the management of the company consider that in the public view the smell of carbolic acid amounts to a conviction that something really sanitary has been done, and that if no evidence is left behind in the shape of a distinctive smell the company might be regarded as having been neglectful in applying common hygienic measures. We doubt whether the application of chemical germicides in the quantity, perhaps in soaps, which is employed has so good an effect as a thorough airing of the compartment, a careful washing of the floors and window frames, coupled with a good dusting of the cushions, preferably by a powerful vacuum plant. It is fairly certain that the merest traces of carbolic acid, as indicated by the faint but sickly smell which is left behind after the performance of a cleaning process by carbolic preparations, cannot be trusted to keep the air for any practical purpose permanently free from obnoxious germs. Apparently the treatment is reserved for third-class compartments, since the carbolic smell at any rate is seldom observable in the first-class carriage. Of course, the crowded portions of the train are in most need of disinfection, but surely it is not necessary to do this in a way suggestive of lavatory cleansing. If, too, the use of a germicide fluid is insisted upon, there are plenty of agents which would be equally effective, while infinitely more agreeable for the purpose.

FIBROSITIS.

THE discussion which recently took place at the Balneological and Climatological Section of the Royal Society of Medicine[1] on the subject of the affection to which Sir Williams R. Gowers gave the name of fibrositis serves as a reminder that in respect of one at least of the conditions to which the name of rheumatism has been applied our knowledge has become considerably clarified of late. It is to Professor R. Stockman that the accepted views on the pathology of this malady, more commonly known perhaps as muscular rheumatism, are principally due. He has shown that underlying the phenomena of pain and tenderness in the muscles there is a definite anatomical lesion consisting in a development of newly formed fibrous tissue situated in the fibrous attachments of the muscles and in the connective tissue lying between the fibres. Accompanying this proliferation there are also an endarteritis and periarteritis of the nutrient vessels. This suggests that the exciting cause is an irritant conveyed by the blood-vessels, though the actual agent at work has so far eluded observation. Mr. K. W.

---

Goadby has now endeavoured to supply this gap in our knowledge and to identify the bacterium producing the inflammatory reaction He finds that if cultures are taken from the urine after massage of the affected parts, organisms are obtained corresponding with some of those which are found in septic conditions of the mouth, notably various streptococci, the diplobacillus necrodentalis, and a peculiar organism which gives rise to oat shaped forms, the streptobacillus male If this discovery is confirmed, we have a piece of more distinct evidence than has hitherto been available in favour of the reality of the danger of articular and other lesions said to exist in the subjects of oral sepsis A gouty disposition seems to act as a predisposing cause of the malady, and atmospheric changes and intestinal disorders may excite attacks Muscular over exertion also acts as an exciting cause, though gentle exercise is one of the most effective modes of treatment for the developed condition In the attacks the affected muscles show increased tonus, the foci of inflammation keeping up a condition of irritation clinically evinced in the form of pain and spasm The occurrence of the lesions of this disease in the muscle of the heart is a possible extension of serious import That they may so occur is not yet proved, but Dr James Mackenzie suggests this explanation of certain cases of the disease in which the auricles and ventricles may be found beating at unequal rates, a condition which points to involvement of the conducting bundle of His in some morbid process

THE THYROID TREATMENT OF DUPUYTREN'S CONTRACTION

AT a meeting of the Académie de Médecine of Paris on Jan 14th a new method of treating Dupuytren's contraction of the palmar fascia was described by M Gilbert It consists in the administration of thyroid extract which he has used in 7 cases with 5 favourable results The following is an example In March, 1911, a locksmith was seen for bilateral contraction of the palmar fascia which began eight years before in the left hand and five years before in the right In the right hand there were hard bands, and the third and fourth fingers were flexed on the palm A similar condition was present in the left hand, but the bands were not so hard or prominent After the administration of nine doses of 10 centigrammes of thyroid extract the right third and fourth fingers could be stretched, and after the administration of 39 doses the hand had regained all its power The treatment was discontinued for three months, and there was then a tendency to retrogression On resuming the treatment rapid improvement took place After taking 163 doses all stiffness had disappeared In May, 1912 the patient was working 10 hours daily, and his hands were no longer stiff after work, and the indurated tissue was softening In June (after taking 216 doses) the tissue was quite supple In the other four cases a similar result was obtained The indurated tissues became softened and the function of the hands was regained In the two cases in which the treatment failed the retraction was very marked and the treatment was continued only for a short time These results point to a thyroid origin of contraction of the palmar fascia This view is borne out by the existence in these cases of other symptoms of thyroid deficiency—subacute "rheumatism," pains, headache, alopecia, and œdema, which were also improved by the treatment In connexion with this view of the pathogenesis of Dupuytren's contraction it is interesting that M Amat has described the case of a soldier whom he cured with iodine It is also interesting that a similar beneficial action on other scleroses has been attributed to thyroid extract in some forms of scleroderma and chronic rheumatism M Gilbert's treatment seems worth a trial

Surgeon General William May, C B, has been appointed Medical Director General of the Navy, in succession to Surgeon General Sir James Porter, K C B

THE LADY SEDLEY'S RECEIPT BOOK, 1686, AND OTHER SEVENTEENTH CENTURY RECEIPT BOOKS[1]

BY LEONARD GUTHRIE, M D OXON, F R C P LOND

THE Lady Sedley's Receipt Book is a MS quarto volume bound in vellum The date 1686 appears on the cover, and on the first page is inscribed with elaborate pen flourishes "The Lady Sedley, Her Receipt Book, 1686" It consists of 75 folios containing 140 recipes, of which 124 are medical and the rest are culinary or cosmetic The handwriting on the first 58 pages is good and clear, the lines are ruled and the headings ornamental, every prescription is numbered Towards the end of the book the prescriptions are in different and more illiterate handwriting, which shows signs of haste or carelessness There is no index The book is of some historical interest for the Lady Sedley by whom or for whom it was compiled, was the wife of Sir Charles Sedley wit writer of plays and sonnets, and boon companion of Charles II Their only child was the notorious Catherine Sedley, mistress of James II, and created by him in 1686 Countess of Dorchester

Prescriptions, many of which are endorsed "Probatum est," or "It hath very often been proved" are supplied for major ailments such as dropsy, palsy renal colic, ague, plague, jaundice (black and yellow), bite by mad dog poison, small pox, scurvy, convulsions, gout, consumption, fistula, and rickets There are also prescriptions for piles, gripes, incontinence of urine, cough epistaxis, sore breasts and eyes toothache tetters (or herpes), "rising of the lytes (or lungs) headache, constipation, shortness of breath and "heate of the liver" The "cosmetics" include applications to make hair grow, or to take it away; for the "morphew" or "freckles", for the cure of "a redd face", to make the teeth white, and to help a "stinking breath" Several of the recipes are by such eminent physicians as Sydenham, Sir Thomas Witherley, Sir Edward Greaves, Lower, King, Hintent, and Stephens

Sydenham's prescription is "for the head" and consists of Venice treacle to the 72 ingredients of which he added wormwood, candied orange peel and angelica, and syrup of candied citrons The dose was the quantity of a nutmeg washed down with a diuretic draught of horseradish juniper, and broom Sir T Witherley supplies a "Dyett drinke for the Gout," chiefly composed of sarsaparilla sassafras harts-horn ivory, flints balsam of tolu and some say the has a receipt for scurvy, containing dock roots hartstongue, and dandelion infused in small ale Other remedies for scurvy have in them sea scurvye grass, watercresses, brook lime and the best (for scurvy and dropsy) contains the juice of 12 fresh lemons Dr King is responsible for a receipt for "the griping of the Gutts" "Take a penny loaf and slitt it and toast it and spread it over with Venice Treacle, and dip it in Sack boyled with Cloves Cinnamon and Nutmegg, tye it up in a cloth and lay it hot to the navel" King, Witherley and Lower attended Charles II on his death bed, and King was the physician who bled His Majesty at the onset of his illness with "extraordinary dexterity resolution, and presence of mind or he had certainly died that moment" (Evelyn) The Privy Council voted him £1000 for so doing, which however was never paid Dr Jacob of Canterbury's medicine for the stone is "15 graines of goat's blood in powder, drinke every morning in Ass's or other Milke"

One recipe is introduced with great parade as "A copy to make the sov'reignst water that ever was devised by man which Dr. Stephens, a physician of great cuning and of long experience, did use and therewith did many great cures, and all was kept in secret until a little before his death, when the Archbishopp of Canterbury gat it from him as follows:—Take a gallon of Gascoyn wine, then take ginger, Gallingall Camell, Cinamint, Tollianders, Nutmegs, Cloves, Aniseed of each one dram, then take Sage, Mint, Red Roses, Thyme of the Moor, Pellitory of the wall, Rosemary, wild Marjoram, Pennyroyal, Thyme, Lavender and Avens." All these were to be bruised together and distilled in a limbeck. "The virtues of this water be these: It comforteth the Spiritts Vitall, and preserveth greatly the youth of man, and helpeth the inward diseases coming of cold, and against shaking of the palsey, it cureth the contraction of the sinewes, it helpeth the conception of women that be barren, it killeth wormes in the body, and killeth the cold gout, and helpeth the toothache, it comforteth the stomach very much, it cureth the cold dropsy, it helpeth the stone that is in the bladder, and in the reines of the back, it cureth the canker, it helpeth shortly a stinking breath, and whosoever useth this water ever and anon, and not often, it preserveth him long in good liking, and shall make one seem young a long time." This Dr. Stephens died aged 98, after being bed-ridden for ten years. He was the author of a catalogue of the Oxford Botanical Gardens. It was Archbishop W. Laud (beheaded in 1645) who got the prescription from him, and afterwards presented it to the "Queen's Closet Opened,"[1] and it was subsequently included in "Quincy's Dispensatory" for 1739.

---

[1] Abst Society

Sir Edward Greaves, the first medical baronet, contributes a receipt for convulsions containing dead man's skull, peonie roots, amber, and bezoar stone. For "giddiness in the head" Dr. Jacob recommends male peonic root and peacock's dung in powder, with nutmeg and black cherry water. We find several prescriptions for rickets, first described by Whistler in 1645, and in 1650 by Glisson in a lengthy treatise. They are "dyett drinkes" containing figs, raisins, currants, various "anti-scorbutics," such as scurvy-grass, licorish, watercress. In one the constituents are to be infused in "faire water," in another the strongest ale and muscadine are employed. Recipes are also culled from non-medical sources. Thus, the Duke of Monmouth and Judge Ellis give remedies for stone, and the Lady Mildmay an "excellent drink for to cure a fistula; but for 'speedy cure' you may tent the wound or sore, and lay thereon a Colworth leaf." Sir Kenelm Digby's "Aqua Mirabilis" finds a place here, and was incorporated in the "Colledge" Dispensatory. It is an infusion of spices in white wine, and was designed to serve as many purposes as even Dr. Stephens's celebrated water.

On the whole, Lady Sedley's recipes are less loathsome than many of those contained in the London Pharmacopœias of the period, for most of them are simple herbal infusions. The excrement and urine of almost every animal were used in medicine, and Willis himself spoke of infusion of fresh horse-dung as "a vulgar but no contemptible remedy in pleurisy and jaundice," and says that fæces of birds and animals owe their value to the volatile salts which they contain. Besides Dr. Jacob's prescription of peacock's dung and peonie for giddiness, Lady Sedley gives infusion of fresh sheep's ordure in Rhenish wine for "black jaundice." Full directions are also supplied for making "Snayle water," distilled from snails and earthworms, and for "Oyle of Swallows," made by pounding in a mortar young swallows just able to fly, boiling them in fresh butter, and straining the result for use in cases of contracture of sinews. Dr. Hintent's preservation against plague consists in forming an issue on the inner side of the left forearm "for the purgeing away from the heart all evil humors which causeth the infection of the Plague." There are several "Plague Waters," all of which contain ginger and some spices which would impart a sensation of warmth to the epigastrium, and thus inspire persons in dread of contagion with faith in the efficacy of the remedy. For small-pox several posset drinks are prescribed with the direction, "Give no medicine when they break otherwise than to wash the eyes and throat with Rose water."

Other MS. Receipt Books of the Seventeenth Century.

The Lady Sedley was not singular in compiling her "Receipt Book." Probably many such are hidden away in the libraries of old country houses. Several interesting examples of the kind are in the MS. department of the British Museum. The most important of these are by Mary Doggett and Lady Ranelagh. "Mary Doggett, Her Book of Receipts," 1682 (Sloane 27,466), large 4to, folios 307, is beautifully written and contains both medicinal and culinary recipes. A MS. note on the first page states that "this Mary Doggett was the wife of Doggett the Player, who left a legacy of a yearly coat and badge to be rowed for." The competition for Doggett's coat and badge by Thames watermen still takes place in August annually, and was inaugurated by Thomas Doggett in 1716.

"The Lady Ranelagh's Choice Receipts, as also Some of Captain Willis's who Valued them above Gold" (Sloane 1367), is a long narrow volume containing 83 folios and 292 recipes. The handwriting is small and cramped, but legible. Like the others, it contains medical, culinary, and cosmetic preparations. At the end there are alphabetical lists of herbs and their virtues, an index to recipes, and also a list of symbols for different drugs, and of "our own abbreviations." The book is undated, but was probably written between 1670 and 1680. Lady Ranelagh was a daughter of the Earl of Cork, sister of Robert Boyle, and of Mary Countess of Warwick. Of Lady Warwick (1625–1678) we are told in a funeral sermon by her chaplain, Dr. Walker, that "if any were sick or tempted, or in any distress of body or mind," they would go to "the good Countess whose closet or still house was their shop for Chirurgerie and Physick." Elizabeth Walker (*née* Sadller), the wife of Dr. Walker, chaplain to the Warwicks, "had a competent measure of knowledge both in physick and chirurgerie," partly obtained from her brother-in-law, "a very able doctor of the London College; and also from her studies of Riverius, Culpepper, and Bonettus." She had "good store of vomits, purges, sudorifics, cordials, pectorals; almost every kind of syrups, strong and simple distilled waters, several quarts of which she left (yea, gallons of which she used most) which it is a pity should be lost" ("Holy Life of Mrs. El. Walker," by Anthony Walker, 1690). Probably these three learned ladies collaborated in producing "Lady Ranelagh's Book of Receipts."

Another MS. (Sloane 556) is "A Booke of Medicens collected, being most of them proved Medicins to healp, written by Mr. Anthony Lewis the 20th day of January 1696 out of a booke which was the La. Marquies Dorsetts." It includes medicine, cookery, and farriery. Anne, daughter of the Earl of Cumberland, married first Richard, Earl of Dorset, and secondly Philip, Earl of Pembroke in 1675. A portrait painted of her during widowhood provides her with two recipe books, and another, painted when she was 13, contains a large assortment of learned volumes. In "Home Life of English Ladies in the 17th Century" (1861) there are many examples of noble ladies who spent most of their time in practising medicine and surgery on their poorer neighbours. Marvellous were the cures of the Countess of Arundel (1557–1630). She turned her house into a hospital, and received patients from places distant 30 or 40 miles. "In some years three score dozen sheepskins were spent merely in making the plaisters she gave, and above 1 cwt. of one matter only, whereof some were made" ("Life of the Hon. Lady Anne Countess of Arundel," by H. G. F. Howard (Duke of Norfolk), 1857, p. 213). Lady Maynard, according to Bishop Ken, who preached her funeral sermon in 1684, "was a common patroness to the poor and needy, and a common physician to her sick neighbours." From Lady Anne Halkett's Autobiography (Camden Society, 1875), 1622–1699, we learn that she was addicted to medical pursuits, and so also were Lady Vere of Kirby Hall and many others of the same period.

It is highly probable that these aristocratic amateurs in medicine were not altogether popular with the faculty, and this accounts for Sydenham's rather ungracious remark: "Nowadays every house has its old woman a practitioner in an art which she never learnt, to the killing of mankind." Dr. Walter Harris also complained of "the cordials which her Ladyship exhibits promiscuously in every disease with very great applause, for be the event what it will, the cordial to be sure must never be blamed" ("De morbis acutis infantum," 1689).

---

[1] So stated in the index of authorities in the "Queen's Closet Opened." But as Laud was beheaded in 1645 it follows that either the compiler of the index made a mistake, or that Lady Sedley was incorrect in saying that Stephens divulged his secret to the Archbishop "a little before his death."

Printed Receipt Books of the Seventeenth Century

Many of the recipes coaxed or stolen from physicians, or handed down for generations from one to another, found their way into print in the seventeenth century The first of these is by Elizabeth Grey, Countess of Kent, 1581–1651 It is entitled "A choice Manual of rare and select Secrets in Physick and Chyrurgerie, collected and practised by the Countess of Kent (lately dec'd)" Although this book went through 19 editions it appears to be rare, for no copies are to be found in our London medical libraries The earliest in the British Museum is the second edition, edited by W Jar in 1653

"The Ladies Cabinet Enlarged and Opened, containing Many rare Secrets and Rich Ornaments of several kinds and different Uses, Compiled under three general heads — (1) Preserving, Conserving, Candying, etc , (2) Physick and Chyrurgery, (3) Cookery and Housewifery, whereunto added Sundry experiments and Choice Extractions of Waters, Oyles, etc Collected and practised by The late Right Honourable and learned Chymist The Lord Ruthven," is a pretty little 12mo book, the second edition of which was published in 1655 It therefore precedes the "Queen's Closet Opened," which Dr Oxford tells me was first published in 1657 "The Queen's Closet Opened Being Incomparable secrets in Physick, Chyrurgery, Preserving, Candying, etc , which were presented to the Queen by the most experienced Persons of the times, many whereof were had in esteem when she pleased to descend to private Recreations" is divided into three parts (1) "The Pearl of Practice," (2) "The Queen's Delight,' (3) "The Compleat Cook" A table of authorities gives the names of 25 physicians several surgeons, an oculist, and a large number of Royal and titled persons who contributed medicinal and other recipes

"The Ladies Dispensatory, Containing the Nature, Virtues, and Qualities of all Herbs and Simples usefull in Physick, reduced into a Methodicall Order, for their more ready use in any Sicknesse, or other accident of the Body, the like never published in English," is by Leonard Sowerby and was published in 1652 The author says in his preface that it is based on the works of Dioscorides, Gerard, Gorœus and Fuchsius At the end there is an alphabetical index or "Table of the Virtues of the Simples contained in this Booke" It is comprehensive, for it contains remedies suitable for the treatment of "The Bitings of Shrew Mice," "The Bitings of Crocodiles, and Cockatrices,' "The Venomes of Toades and greene Froggs," and of other reptiles and noxious insects

It is evident from the existence of these popular "Receipt Books" that anyone who chose to collect a sufficient number of "formulas" was considered fully equipped for the treatment of diseases of all kinds And if like Sydenham and *Harris we are inclined to cavil at the claims of noble ladies* to "practise an art which they had never learnt, to the killing of mankind," we must nevertheless remember the woeful plight of therapeutics at the time The simple herbal remedies of the Lady Sedley and her like were harmless in themselves, and not a whit less based on ignorance and gross superstition than many which they prized as bearing the stamp of highest medical authority

Historical Details

A few more details regarding the Sedley family may not be out of place Samuel Pepys makes many uncomplimentary allusions to Sir Charles Sedley's mad pranks and dissolute behaviour In 1663 Sedley, Lord Buckhurst, and Sir Thomas Ogle got drunk at the "Cock" in Bow street, and caused a riot by their grossly indecent conduct, for which Sedley was fined £500 In 1668 he and Lord Buckhurst again scandalised everybody by running about the Strand "sans culottes" On this occasion the King took their part, and Pepys feared that the Lord Chief Justice Keeling would "lay the constable by the heels" for daring to arrest these fine gentlemen Again, in October, 1668 Pepys alleges that the King, Sedley, and Buckhurst were all drunk together at Saxham Pepys, however, admits that with all his faults Sedley was a "mighty witty man" According to his biographer, "the King would never part with Sedley, so he never would part with the King" although "his estate was never the better for the Court," and "his morals much the worse" Charles II liked him because he never asked him for anything, and also "singled him out for the best genius *of the age, and frequently told his familiars that Sedley's* style either in writing or discourse would be the standard of the English language" His published works hardly bear out Charles's estimate of them, but he is still remembered as the author of the charming sonnet, "Phyllis is My Only Joy" His verses are neat, simple in diction, and not quite so coarse as those of Rochester, Buckingham, and in places even Cowley Rochester summed them up appropriately enough as "mannerly obscene" His plays, of which "Bellamira" or "The Mistress" has been accounted the best, are both tedious and licentious

In 1680 Sedley met with an accident thus recorded in the "Hatton Correspondence" (Camden Society, Vol I, *p 216) "Jan 15, 1679 80 Yesterday ye roof of ye Tennis* Cote in ye Haymarket fell down Sr Charles Sidley being there had his skull broke, and it is thought it will be mortall" It may have been partly on account of this accident, or for domestic reasons that Sedley withdrew as much as possible from London after the death of Charles II , but he did not retire from political life Several of his speeches in Parliament as Member for New Romney are included in his printed works A passage from the last of these, delivered in 1699 during a debate on "a Bill for disbanding the Army," will bear quotation It ends "If we are true to ourselves 10,000 men are enough , and if not, 100 000 men are too few" He died in 1701

Catherine Sedley daughter of Sir Charles and the Lady Sedley, was born in 1657 Evelyn described her as "none of the most virtuous but a witt" She was pale, squinted, and was otherwise so plain that Charles II said that he supposed she was prescribed to his brother James by his confessor as a sort of penance However she seems to have exercised a singular fascination over James, and the Protestants made use of the *liaison* for political reasons The climax was reached when she was created Baroness Darlington and Countess of Dorchester, with an income of £5000 a year, on Jan 19th, 1686 This was a deadly insult to the Catholics, and Queen Mary was so furious that she went on "hunger strike" for two days James only *succeeded in persuading her to take food by scourging* himself in her presence The Queen kept the scourge, but the Countess eventually got the money She was, however, ordered to withdraw from Whitehall and advised to pay a visit to Flanders She objected to Flanders on the ground that the 'number of Convents there would render the air too oppressive" and went to Ireland instead But not liking Dublin, she returned to London in August, 1686 James immediately fluttered back to her side, but the reunion did not last long Her political influence was gone, and her income for the time remained unpaid Her father does not seem to have been on good terms with his august "son in law" He was instrumental in procuring the accession of William and Mary, and remarked afterwards that he and James were even for "if he has made my daughter a Countess, I have helped to make his daughter a Queen" In return for Sedley's good offices the countess received a grant of £1500 a year from William and Mary in May, 1691, and in 1703 her original pension of £5000 a year was renewed by a grant of the Irish Parliament She married Sir David Colyear (afterwards Earl Colyear) in 1696, became pious, it is said, and died at Bath in 1717.

Of the Lady Sedley herself, we have little information beyond that which may be inferred from the "Receipt Book ' which she compiled There is a note, however, concerning her in Burnet's "History of My Own Times ' (Vol III , p 114) which is of interest Referring to her daughter, Lady Dorchester, the editor "D" writes 'The best excuse that could be made for her was that her mother Lady Catherine Sedley had been locked up in a madhouse many years before she died" But it is clear that she must have been in full possession of her senses in the year 1686, when her book was commenced As we have seen, the year 1686 marked an important epoch in the lives of the Sedley family, for it coincided with the retirement of Sedley from the Court, and with the social ostracism of the Lady Dorchester The inception of her book suggests that poor Lady Sedley was prepared to welcome the return of her wayward husband and erring daughter to the family fold at Southfleet. Surely, her famous "*Cordialls*" and "*wound waters,*' her cures for ailments of the head, stomach, liver, and kidneys, were designed to patch up the damaged constitution of the one, whilst her face washes, unguents, and cosmetics might serve to impart to the other some of the loveliness which Nature had denied her. Moreover, in order to keep her wanderers to her side, she must feed them well, and hence her excellent recipes for table delicacies. Such reflections lead us to attach a faint tinge of romance to the faded pages of "The Lady Sedley's Receipt Book."

THE MENTAL DEFICIENCY BILL.

THE Bill which the Government hopes to see placed upon the statute book as the Mental Deficiency Act, 1913, has the advantage over its predecessor of having had its subject matter discussed and defined by the House of Commons during last session, and of having had eliminated from it features which were likely to secure for it considerable opposition. For example, it makes no reference to the undesirability of procreation of children by the mentally defective, and the passage which in the former Bill sought to make penal marriage with a defective person, knowing that person to be defective, and also to penalise anyone knowingly solemnising or bringing about such a marriage, has gone. The omissions will be received with mixed feelings even by those who allow their convenience.

Defining Clauses.

The various changes made in the original Bill in committee have been noticed from time to time in THE LANCET, but it will be useful to quote in full the two defining clauses which are now found at the beginning instead of towards the middle of the proposed measure. It will be observed that certain persons, under Clause 1, are to be regarded as mentally defective within the meaning of the Act—this definition was given in our Parliamentary Intelligence last week—but such persons are only to come under the authority of the Act on the fulfilment of conditions prescribed by Clause 2:—

1.—The following classes of persons who are mentally defective shall be deemed to be defectives within the meaning of this Act—

- (*a*) Idiots; that is to say, persons so deeply defective in mind from birth or from an early age as to be unable to guard themselves against common physical dangers;
- (*b*) Imbeciles; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness not amounting to idiocy, yet so pronounced that they are incapable of managing themselves or their affairs, or, in the case of children, of being taught to do so;
- (*c*) Feeble-minded persons; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness not amounting to imbecility, yet so pronounced that they require care, supervision, and control for their own protection or for the protection of others, or, in the case of children, are incapable of receiving proper benefit from the instruction in ordinary schools;
- (*d*) Moral imbeciles; that is to say, persons who from an early age display some permanent mental defect coupled with strong vicious or criminal propensities on which punishment has little or no deterrent effect.

2.—(1) A person who is a defective may be deal with under this Act by being sent to or placed in an institution for defectives or placed under guardianship—

- (*a*) at the instance of his parent or guardian, if he is an idiot or imbecile or is under the age of 21; or
- (*b*) if in addition to being a defective he is a person—
  - (i.) who is found neglected, abandoned, or cruelly treated; or
  - (ii.) who is found guilty of any offence, or who is ordered or liable to be ordered to be sent to a certified industrial school;
  - (iii.) who is undergoing imprisonment (except imprisonment under civil process), or penal servitude, or is undergoing detention in a place of detention by order of a court, or in a reformatory or industrial school, or in an inebriate reformatory or who is detained in an institution for lunatics or a criminal lunatic asylum; or
  - (iv.) who is an habitual drunkard within the meaning of the Inebriates Acts, 1879 to 1900; or
  - (v.) in whose case such notice has been given by the local education authority as is herein-after in this section mentioned; or
  - (vi.) who is in receipt of poor relief at the time of giving birth to an illegitimate child or when pregnant of such child.

Part 2 of Clause 2 further provides for notice being given to the local authority by the local education authority with regard to defective children over the age of 5 years who are incapable of receiving benefit from special instruction, and with regard to children too old to remain at school and needing to be placed in institutions or under guardianship.

Manner of Dealing with Defectives.

The rest of Part I. gives power to deal with defectives in the following manner, and provides the necessary legal machinery for their protection. The parent or guardian of a defective who is an idiot or imbecile or under the age of 21 years may place him in an institution or under guardianship, subject to a certificate in prescribed form from a medical practitioner. A defective subject to the Act may at the instance of one not his parent or guardian be dealt with (*a*) under an order made by a judicial authority on a petition; (*b*) under an order of the court if found guilty of an offence or liable to be sent to an industrial school; (*c*) under an order of the Home Secretary in the case of a defective detained in a prison, criminal lunatic asylum, reformatory or industrial school, place of detention, or inebriate reformatory. A petition seeking an order from a judicial authority in respect of a defective must be accompanied by two medical certificates or by a certificate that a medical examination was impracticable, and by a statutory declaration setting out certain prescribed particulars. The effect and duration of detention orders and of detention not under orders are dealt with in Clauses 10-12.

It may be noted that in Clause 8, which lays down the procedure in cases of defectives guilty of offences, it is provided that when prisoners apparently defective are charged with offences, the police are assigned the duty of communicating with the local authority and of bringing evidence as to the prisoner's mental condition before the court. Provision is also made for the transfer of defectives undergoing imprisonment, or otherwise under unsuitable treatment, to institutions for defectives. By Clause 14 provision is made for taking to a place of safety any person believed to be defective and not properly taken care of, and in cases of suspected neglect or cruelty, a magistrate's warrant may be obtained enabling a constable to make a search and to obtain forcible entry, if necessary, into a house and remove the defective person. In these circumstances the constable is to be accompanied by the medical officer of the local authority or by some other medical practitioner. Transfers from institutions for defectives to institutions for lunatics and *vice versâ* are duly provided for.

Constitution of Central and Local Authorities.

The central and local authorities for the administration of the Act are dealt with in Part II., Sections 19-32. The central authority is to be known as the Board of Control, and is to consist of not more than 15 commissioners, not more than 12 of whom are to be paid, and of the paid commissioners four are to be legal and four medical commissioners, in each case of not less than five years' professional standing. One paid and one unpaid commissioners are to be women. The Lord Chancellor is to appoint the legal commissioners after consultation with the Home Secretary, and the latter gentleman, after consultation with the Lord Chancellor, is to appoint the others. The existing Commissioners in Lunacy are *ex officio* to be members of the Board of Control when the Act comes into force, and the Board is to superintend the supervision, protection, and control of defectives, powers exercisable with respect to lunatics by the Chancellor, Lunacy Commissioners, judge or masters in lunacy, and others, continuing to be so exercised by them except where it is expressly provided otherwise by the Mental Deficiency Act. Express provision thus referred to is to be found in Clause 59, which provides that "all the powers and duties of the Commissioners in Lunacy under the Lunacy Acts 1890 to 1911 shall as from the commencement of this Act be transferred to the Board, and His Majesty may by Order in Council direct that anything which under those Acts is required or authorised to be done by, to, or in respect of, any one or more Commissioners in Lunacy or any officer of those commissioners, shall be done by, to, or in respect of one or more commissioners under this Act or the corresponding officer of the Board. Provided that nothing in such Order in Council shall authorise anything by those acts required to be done by two commissioners, one a medical commissioner and the other a legal commissioner, to be done otherwise than by two commissioners so qualified." The powers and duties of the Commissioners of the Board of Control are defined, and include the supervision, inspection, and visiting necessary to make the Act effective, and the maintenance by the Board of institutions for defectives of criminal, dangerous, or violent propensities. The local authorities for the purposes of the Act are to be, by Clause 25, the county and borough councils for counties and county boroughs respectively, and every local authority is to constitute a committee for the care of the mentally defective consisting of members of the council and other persons having the requisite knowledge and experience The general powers of the local authorities include the ascertaining who within their area are defectives or subject to be dealt with under the Act, and to provide for them suitable supervision, or to secure their being sent to institutions or placed under guardianship, power being given to make provision for guardianship or to maintain the defective person wholly or partly in an institution

Clause 29 defines the duties of the local education authority under the Act with regard to defective children and to the information to be given to the local authority with regard to them

Provision of Institutions, Penalties, &c

Part III of the Bill dealing with "the Supervision and Provision of Institutions, &c, shows that the following classes of institutions are contemplated and provided for ' State institutions," established by the Board for those of criminal, dangerous, or violent propensities, "certified institutions' being institutions maintained for the care and treatment of defectives subject to certification and supervision by the Board, in which are included "approved buildings," provided by boards of guardians for those under their charge, "certified houses,' kept by persons receiving defectives for their private profit, "approved homes, which may be instituted by the managers of any institution for defectives supported wholly or partly by voluntary contributions, or by persons receiving defectives for profit Defective persons who are maintained in certified houses will not receive any contribution to their expenses from money provided by Parliament or from local authorities, and approved homes will not be for any person sent to an institution by judicial order, or by a court, or by the Home Secretary Local authorities, subject to the approval of the Secretary of State, may establish or contribute to institutions, or contract with managers of certified institutions for the reception and maintenance of persons for whom they are required by the Act to make provision The Home Secretary is empowered to make regulations as to the granting of certificates to institutions for their organisation and management and for other matters affecting the reception, discharge, and welfare of their inmates

Part IV of the Bill provides the necessary penalties for infringements of the Act and for offences with respect to the reception, detention, and general treatment of defectives Except in such institutions or places as have been mentioned no one may undertake the care of more than one defective, and where such care of one defective is undertaken notice must be given It will be a misdemeanour for any manager of an institution, owner of a certified house, or guardian of a defective, to detain him or exercise powers over him conferred by the Act after he has knowledge that those powers have expired Among other matters it may be mentioned that suitable provisions are made to prevent the supply of intoxicants to defectives who are being cared for under the Act, to punish ill treatment of them and the abuse of females Offences under the Act may be punished by fine or imprisonment not exceeding two years or upon summary prosecution by three months imprisonment, or by fine not exceeding £50

Due provision is made for the transfer of the staff of the Lunacy Commissioners to the Board of Control, for financial and for other matters Among definitions it may be noted that "relative means a lineal ancestor or lineal descendant of an ancestor not more remote than great grandfather or great grandmother" The Bill does not extend to Scotland or Ireland, and is designed to come into force on Jan 1st, 1914 It is, however, obviously a measure which will take some time, possibly some years to become fully effective We comment upon some of its principle features in a leading article this week

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR, ISLE OF WIGHT —The annual general meeting of governors of this hospital will be held at the Whitehall Rooms, Hotel Metropole, London, S W., on Thursday, April 24th, at 3 P M, when matters of importance to the institution will be considered

---

ANNUAL REPORT OF THE LONDON COUNTY COUNCIL FOR 1911.

IN THE LANCET of March 15th the appearance was announced of Volume III of this report, which relates to matters of public health[1] In a preliminary article of that date we reviewed Chapter XXXII, which deals, *inter alia*, with the Vital Statistics of London for 1911, compiled by Dr W H Hamer, the county medical officer of health In the present article we deal with Chapter XXXIV, which includes the report for 1911 of Dr James Kerr In presenting this report the Education Committee point out that in July, 1911, the Council decided to place under the control of the county medical officer of health the medical work of the Education Department From the circumstance that Dr Hamer did not enter upon his duties as county medical officer of health until the beginning of 1912 it follows that for the views expressed by Dr Kerr on the medical work of his department in 1911 he alone must be held responsible

Report of the Medical Officer (Education) for 1911.

Dr Kerr's report is an elaborate and comprehensive document of 78 pages It abounds with matter of consummate importance to the rising generation of Londoners In all probability some of the writer's conclusions will fail to obtain universal approval, nevertheless, they are deserving of respect, as the product of his long and unique experience. For the latter reason we believe that the report will be studied with advantage by the large body of school medical officers newly appointed throughout the country

'With this report' says Dr Kerr, 'the series for which I have been responsible during the last ten years is concluded An attempt has been made to lay the foundations of school hygiene as a study of national interest and value on the basis of problems worked out on scientific lines by the staff of the department" Adverting to the circumstance that from the close of 1911 all arrangements for medical treatment have been transferred from the education officer to the medical officer of health, Dr. Kerr acknowledges that the change can be justified, if it is regarded as a first step to the coördination, under one authority, of the sanitary service of the metropolis. Dr Kerr is careful to insist that, in matters of school hygiene, existing knowledge is still far ahead of practice. He expresses the conviction that under present-day conditions schools play only a minor part in the dissemination of the more familiar infectious maladies, and on that account urges what he considers the superior claims of sanitation in the home The stuffy conditions of dwelling rooms and the scarcity of playgrounds he regards as answerable for the excessive prevalence among children of adenoids, as well as of anæmia and debility Observing that school hygiene has already passed beyond school limits, in the wide outlook derived from the study of children there, he rightly declares it a matter of urgent national importance that, in addition to better food and improved opportunities for cleanliness, greater space for living and recreation purposes should be provided for children of school age Particularly instructive to medical officers newly undertaking school work are the sections on medical inspection and treatment, which are ably written, and will repay attentive study

Medical Inspection of School Children

[illegible] 00 children, in round numbers, [illegible] in London during 1911, more [illegible] various kinds and that of these two thirds were recommended for treatment One third of the children were the subjects of enlarged tonsils or adenoids, and four fifths of dental caries Between two and three thousand cases of ringworm came under observation during the year The returns of re inspections of children recommended for [illegible] received treatment [illegible] 4000 unsatisfacto[illegible] under treatment Since 1908 medical inspection has been carried out in all the secondary schools, training colleges, and technical schools of the Council The students are continuously under observation; and in case of illness they are debarred from further residence in the institution. Medical inspection is now regarded as an indispensable and generally acceptable detail of school routine. The masters and mistresses for the most part show keenness and promptitude in obtaining treatment of ailments noted at the medical examinations, and the parents willingly respond to their efforts. Compared with the previous year, the defects found in 1911 show a considerable decrease, the physique of many previously defective children having materially improved.

[1] This volume includes (1) the Report of the County Medical Officer of Health (2) the Report of the Education Medical Officer, (3) the Report on the Housing of the Working Classes Act. Foolscap folio, pp 193 and lxviii King and Son Price 2s 6d.

Recent experience once more emphasises the contention that good nutrition is essential if the best value is to be derived from tuition. Many of the boys in the "trade schools" improve remarkably under the combination of physical and mental training, but a few of them who come from very poor homes and are insufficiently fed fail to derive benefit. A boy of first-class ability may learn so easily as to get on in spite of a third-class physique. A boy of first-class physique will not be harmed by the endeavour to push on his third-class wits, but a boy of rather poor physique and average intellect will suffer from the strain, as also will those boys who are insufficiently nourished and cared for.

As regards prophylaxis, Dr. Kerr regards the inculcation of habits of cleanliness as a material function of school work. When the want of reasonable opportunities for cleansing is properly appreciated school baths will probably be insisted on as part of the prophylaxis against the lymphatic debility that shows itself ultimately in the shape of adenoids or perhaps of tuberculosis. The reserve powers of children require cultivation. The necessity for free exercise and fresh air proves the want of playgrounds more spacious than those now attached to the schools. If town-bred children are to maintain normal health they must be enticed into playgrounds, and houses will have to be demolished in order to provide the necessary ground-space. Reaction to unhealthy environment is shown by the fact that 30 per cent. of the school children are sufferers from adenoids. Many of these need surgical operations; but, in circumstances existing among school children, even this is unsatisfactory in about two-thirds of the cases. Rational treatment, by preventing ill-health indicated by these symptoms, would involve the use of all means to prevent catarrhal attacks, and to raise the reserve powers of children. Among the chief causes of catarrh in early life are ignorance and dirt. Sufficient air space is the principal need—house room and all that it connotes; school room; free spaces of land for ventilation; opportunity for recreation; the provision of baths and other means of cleanliness. Few people will differ with Dr. Kerr in the opinion that the expenditure of public money on the health of children is of greater national importance than its expenditure on the health of adults.

Medical Treatment of School Children: Enlarged Tonsils and Adenoids.

The treatment of children whose educational efficiency is damaged by dirt, parasites, diseases of the ears, adenoids, or impaired eyesight was begun in London about ten years ago. In a report submitted at the time it was represented to the Council that the treatment of such conditions was then becoming burdensome to the hospitals, and the doubt was expressed whether, even in course of time, this public duty would be efficiently discharged by their means. Our readers know the difficult position which has since ensued, both for the London County Council and the great charities.

Of the cases requiring medical treatment, the children who suffer from enlarged tonsils and adenoids form the majority. Dr. Kerr is of opinion that no teacher should have charge of a class in an elementary school who cannot decide whether or not a child is suffering seriously from this cause. The proportion of children affected in this way varies considerably in different districts and at different seasons of the year. In the Islington schools about one-third of the children were noted by Mr. Cecil Rowntree as having enlarged tonsils or adenoids, and to a serious extent in one-third of these (10 per cent. in all), whilst in 3 per cent. of the total surgical interference was urgently required. Among 1500 children in Chelsea schools 44 per cent. were found to be suffering from enlarged tonsils or adenoids, and surgical interference was reported necessary in respect of not less than 7 per cent. of these. Miss M. H. F. Ivens found among the aliens in the East-end schools that 34 per cent. of those who heard well had "open mouths," whilst of those with discharging ears 78 per cent. were mouth breathers. In many cases mouth breathing persists, even after operation; and among the mentally defective about 50 per cent. on the average are mouth breathers, the habit having been acquired by catarrh in infancy, and persisting from subsequent neglect. As to the results of operation for this condition, the available returns are very disappointing. According to a table it appears that of 400 cases operated upon 237 were returned as unsatisfactory because the mouth breathing persisted. We are told that children are not recommended for operation merely because of the presence of adenoids, but because of such noticeable symptoms as mouth breathing, snoring respiration, nasal discharges, and associated deformities. Two of the cases cited in the report had been operated upon five times for adenoids, and still were not relived because the noses were blocked by hypertrophied turbinals.

And here Dr. Kerr pertinently remarks that "it is not sufficient that provision is made whereby a third of the children who present pathological conditions among the large number with enlarged tonsils and adenoids can be medically or surgically treated ...... while one-third of the children in the schools present conditions which represent a struggle against factors of ill health; the causes must be sought out and removed as a public task. It is not a mere academic inquiry which is now suggested, but a fundamentally important one, which also lies at the root of tuberculosis and other causes of chronic debility."

School Clinics: Examination of Defectives.

Under the Education (Defective and Epileptic Children) Act of 1899 the care and tuition of defective children in special schools were provided for. The medical examination of candidates for admission to these schools is gradually becoming more critical. These examinations, and particularly those of cases presenting special difficulties, constitute a kind of "school clinic." Consequent on the establishment of schools under the Education Act of 1870 the existence was revealed of a considerable number of children who are unable to profit by the education ordinarily provided for them. In 1890 a committee of inquiry nominated by the Charity Organisation Society estimated that 1 per cent. of the children examined were in need of special care and training. The interest aroused by these special schools and by the representations of committees of various societies led to the appointment in 1897 of a special Departmental Committee on Defective and Epileptic Children. This committee reported that "children exist who, on the one hand, are too feeble-minded to be properly taught in elementary schools by ordinary methods, and, on the other hand, are not so feeble-minded as to be *imbecile* or *idiotic*"; and it pointed out that appropriate educational treatment is indispensable for these children. The interest in questions of national physique aroused by the revelations of the South African war and by the reports of the Committees on Physical Education and National Deterioration led to demands for further inquiry, culminating in the appointment of a Royal Commission on Control of the Feeble-minded, the proceedings of which are fully discussed in the present report, to which reference must be made for details.

The Blind and Deaf.

The Education (Blind and Deaf Children) Act of 1893 prescribes the treatment of children whose *sight* is too defective for ordinary schooling. The smallest amount of vision, even if limited to the perception of direction of light, is of some use in life, and should be conserved to the utmost. There is, however, a considerable amount of blindness of such a nature that ordinary schooling is largely lost; whilst education by the usual "blind methods" is of still less value in later life, vision being valuable even in work. Ten years ago a census was made in the schools for the blind. Ophthalmia neonatorum accounted for 30 or 40 per cent. of the blind cases. The disease having at last been made notifiable, blindness from that cause may be expected to fall, in the next decennium, to one-twentieth of its present amount.

Highly important, from the public health standpoint, is analysis of the causes of deafness. Among 874 cases recently reported as deaf, 41 per cent. were returned as congenitally deaf, whilst the cases of acquired deafness amounted to more than half. Among the latter meningitis and other brain diseases accounted for 18 per cent. and acute infectious diseases for over 30 per cent. As a cause of deafness measles is twice as important as scarlet fever. The rarer prevalence of the latter disease as a factor of deafness is due partly to the diminished severity of the disease in recent years and partly to increased attention paid to its prevention by sanitary authorities. To suppurative aural disease not caused by fevers 11 per cent. of the total cases were referred; the majority of these were due to adenoids or to middle-ear catarrh, and most of these were avoidable.

Epilepsy among School Children.

From the report it appears that in London alone about 300 children are constantly debarred from educational benefits on account of epilepsy. Besides these, a certain number of children who suffer from *petit mal* are allowed to remain in ordinary schools, or, where the affection is more serious, in special schools. Some epileptic children are highly intelligent, while others are simply imbeciles. Some are placid, others violent and sometimes insane. For the care and treatment of epileptic children there still continues urgent need for suitable and commensurate provision in the metropolis.

(To be concluded.)

ASYLUM REPORTS.

Croydon Mental Hospital, Warlingham, Surrey (Annual Report for the Year 1911).—The average number resident at this hospital during the year was 651. Sixty-five men and 179 women were admitted. Of these, 8 were congenital cases, 88 had been insane for more than 12 months before admission, 24 had been insane for over three months before admission, and 48 had previously suffered from an attack of insanity and had been insane a second time more than 12 months before admission. Among etiological factors, heredity was traceable in 64 cases. Dr. E. S. Pasmore, the medical superintendent, found an insane history in 55·4 per cent. of the admissions. Of these, 25 per cent. were men and 30·4 per cent. women. A direct inheritance of insanity through father or mother was found in 34 per cent. Of those who have an insane history, only 28 per cent. recover; of those who have no insane history, 46·2 per cent. recover. The recovery rate, therefore, is 18·2 per cent. higher in those who have no inherited tendency than in those who have such a tendency. Fifty persons were discharged recovered. Excluding the 65 chronic cases received as boarders from other asylums, this gives a recovery rate of about 36·8 per cent. The deaths numbered 42. Post-mortem examinations were held in 20 cases. In the remaining 22 cases the friends objected. Pulmonary tuberculosis, heart disease, general paralysis, and pneumonia were the chief causes of death. Dr. Pasmore points out that the majority of those admitted were nearly 12 months afflicted before asylum treatment was sought. In many cases the patients had passed through the hands of charlatans and those inexperienced in nursing. The dread of friends to seek early advice from a mental specialist is due to the horror people have to their relations being certified as insane and sent to an asylum. This evil might be mitigated if the lunacy authorities in every town were to coöperate with the local authorities. A hospital mental clinique presided over by the medical officers of the local asylum might be instituted at every local hospital in the country, near which there is an asylum, but in such a fashion as not to clash with other out-patient departments. Medical officers in turn from the asylum could attend on one or two mornings a week. People might then be attracted to bring their friends to such a clinique, on the first sign of any mental aberration manifesting itself, to seek advice. By this means cases in the earlier stage might be detected, and there would be a chance of immediate cure, while those who became chronically insane could be at once drafted to the local asylum.

City of London Asylum, Stone, near Dartford (Annual Report for the Year 1912).—At this hospital the number under treatment during the year was 755, the average daily number resident being 617. The number of admissions, 139, was smaller than that of the previous year by 11. The number of the admissions at this hospital is not, as in other public mental hospitals, an index of the insanity occurring in a certain district, but depends on the number of vacancies present. Acute melancholia was present in 31 cases, acute mania in 18 cases, general paralysis of the insane in 16 cases, and delusional insanity in 25 cases. Thirty-four patients recovered. The proportion per cent. of the recoveries to direct admissions was 31·77. Thirty-three patients died during the year, and 26 necropsies were made. The proportion per cent. of deaths on the daily average number resident was 5·34. The principal causes of death were general paralysis in 8 cases, and senile decay in 5 cases. There were only 4 deaths from tubercular disease. Sixty-three paying patients were received. Dr. R. H. Steen, the resident physician, reports that a new verandah has been opened recently on the female side. Other verandahs have been in constant occupation by day and night, and the wonder is now frequently expressed as to how it was possible to manage without them in the past. All kinds of mental disease were benefited by the rest of the sufferer in bed in the open air, but it is, perhaps, in acutely maniacal conditions that we see the most remarkable results. Dr. Steen has frequently seen a patient who while in a padded room was noisy, excitable, and destructive, on removal to a verandah become quiet and go off to sleep. With regard to other matters of treatment, the use of the prolonged warm bath has proved, in several cases, to be of service. In general paralysis, urotropine has been employed as a routine measure, and the general impression has been that it is of distinct value.

Ayr District Asylum (Annual Report for the Year 1912).—The total number of cases under treatment at this asylum during the year was 687, or 17 below last year's number, which was the highest ever recorded for this asylum. The admissions numbered 138. The male admissions were 15 less than the average for the county during the past 20 years, while the number for the women was only two more. Of those admitted, over 60 per cent. were in indifferent bodily health and over 35 per cent. were in a very weak and exhausted condition. The figures are indicative of the considerable amount of medical and nursing attention involved in the care of the physical state of the insane. With regard to the curability of those cases admitted, 40 per cent. suffered from conditions involving permanent or progressive mental enfeeblement. No less than 40 per cent. of the cases had shown symptoms of mental disease for over a year before admission to the asylum. Dr. G. Douglas McRae, medical superintendent, points out that it is of the utmost importance to the individual to have early and skilled treatment if a cure is to be effected. The disadvantage to society, on the other hand, in failing to make timely provision, is an accumulation of rate-paid mental cripples, which represents a loss to the nation in *personnel* and pocket. Thus the popular prejudice against early asylum treatment jeopardises the individual and still further burdens the State. With regard to the ages of those persons admitted, 23 per cent. were under 30 years of age, 27 per cent. between 30 and 40, 17 per cent. between 40 and 50, 20 per cent. between 50 and 60; 8 were over 70. Hereditary predisposition to insanity was ascertained in nearly 22 per cent. of the cases. Alcoholic excess obtained also in 22 per cent., either as cause or symptom of the mental malady. This is a considerable improvement on the 52 per cent. of the year before. The recovery rate calculated on the number of admissions for both sexes stands at 40·58 per cent. Twenty-six cases were discharged unrecovered, 24 relieved, and 2 not improved. The number of deaths was 56. Six persons died with tuberculosis as principal or contributing cause. This number is a gratifying reduction in figures for the past five years, from 37 per cent. of the total deaths in 1908 to 10·7 per cent. in 1912.

LITERARY INTELLIGENCE.—Messrs. William Hodge and Company, Edinburgh and London, announce for early publication a new volume in their series of Notable English Trials, entitled "The Trial of Dr. Lamson," edited by Hamilton L. Adam, and illustrated with portraits.—Mr. Edward Arnold is publishing a new work by Professor Robert Saundby, M.D., entitled "Old Age: Its Care and Treatment in Health and Disease."

Public Health.

Public Health at Colombo.

The medical officer of health of Colombo, Dr. William Marshall Philip, reports a generally satisfactory condition in this city during the year 1911. According to a census taken in March the population numbered 212,295, the remarkable increase of 36 per cent. having occurred during the preceding decennium. Of this increase 7 per cent. was due to an extension of the city boundaries. Even with this deduction the actual increase was more than 10,000 above the estimated number. We are not surprised to hear that the housing problem has become so pressing, partly from the indiscriminate and insanitary erection of buildings that has taken place for many years, and partly from this great increase in numbers, that remedial action is urgently required. The course suggested is to follow the examples of Bombay and Calcutta, and create an improvement trust for the city. The sooner this is done the less costly will it be for the ratepayers. The birth-rate was 24·7 per 1000, an increase of 1·6 over the average for the preceding decennium. The infantile death-rate was 316 per 1000 births, a decrease of 22 on the preceding average; but as it is a native custom to migrate from the city shortly before the birth of the child and return soon after, the birth-rate is too low and the infantile death-rate too high. The general death-rate was 33·8 per 1000, an increase of 0·8 on the decennial average; if corrected for deaths in hospital of non-residents the ratio was 30·9. Pneumonia, causing 4·02 deaths per 1000, was the most fatal disease, this rate having only twice been exceeded during the decade; on the other hand, phthisis caused 2·96 deaths per 1000, a lower ratio than in any year of the decennium, and 0·55 below the average. Since 1906 energetic preventive measures have been undertaken, including, *inter alia*, notification of cases and disinfection of houses affected. In the year 1911 there were 364 houses so treated, and it seems only reasonable to attribute the improvement to this vigorous action. Dr. Philip points out that the next forward step is to provide a hospital for the segregation of advanced and infectious cases, with power to enforce removal when necessary. Diarrhœa and dysentery have caused 4·57 deaths per 1000, a decrease of 1·41 on the decennial average, and the fever mortality has also slightly diminished from 2·46 to 2·29 in the year under review. Of enteric fever 1149 cases were reported, with 396 deaths, a ratio of 1·85 per 1000, this being an increase over the decennial figure of 1·18. The case mortality, 38·9 per cent., shows that many non-fatal cases must have escaped notification. Direct contact is considered to have been a frequent mode of spread among the poorer classes; also latrine infection, either directly or through flies. Dr. Philip speaks strongly of the neglect that many householders are guilty of in regard to the state of their servants' latrines. In this he has our entire support. "The more unpleasant a place the servants' latrine is to inspect the more need is there that the householder should do so, and see that proper steps are taken to improve it and to protect both his own and his neighbour's households. If he fails to do so he must be viewed as a menace to public health." Of 900 cases of enteric fever investigated, the latrines were found to be badly kept in 801. Milk was not an important source of infection, none having been taken in 63 per cent. of the cases, and only tinned milk in a further 16 per cent. Dr. Philip strongly recommends inoculation for the young European arrivals in the colony. Of small-pox, 65 cases occurred with 8 deaths, the infection being, as usual, imported from India. Attention is called to the absence of any special staff for carrying out food inspection, this being done by sanitary inspectors, who have many other duties to perform. A very great improvement has taken place in the character of the milk-supply, only 17 per cent. of 1087 samples having been found to be adulterated; whereas in 1907 adulteration was found in 73 per cent. There is a very large consumption of tinned milk, some of which is of very inferior quality: the recommendation of the medical officer that it should be an offence to sell tinned milk, with instructions on the label which if carried out would reduce the milk below the Colombo standard, is most reasonable. Injustice is done to the local milk dealers and injury to the health of infants by the use of inferior brands of milk. Dr. Philip also recommends that tinned meat, &c., should have the date of filling clearly impresse each tin, without which mark it should be lia seizure. In this he has the support of all public authorities. The native laundry arrangements at C are as unsatisfactory as in most places in the Ea know no better solution than that here recommende there should be two standards, one for the ordinary and another and higher standard of sanitation for class *dhobie*, for which the customer must be prep pay at a higher rate. Good work is done in syst municipal cleansing of compounds and especially o latrines, and in dealing with mosquito breeding We congratulate Dr. Philip on the results of a year under the extremely difficult sanitary conditions of Co

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with popul exceeding 50,000 persons at the last Census, and aggregate population at the middle of this year is esti at 17,852,766 persons, 9353 births and 5337 deaths registered during the week ended Saturday, Apri The annual rate of mortality in these towns, whic been 17·0, 16·5, and 16·9 per 1000 in the three pre weeks, declined to 15·6 per 1000 in the week notice. During the 13 weeks of the quarter just end mean annual death-rate in these towns averaged against 17·5 per 1000 in London during the same p The death-rates last week in the several towns ranged 5·7 in Rotherham, 6·6 in Southend-on-Sea, 7·0 in E 7·7 in Ealing, and 7·8 in Portsmouth, to 20·9 in Sto Trent, 21·2 in Plymouth, 22·2 in Middlesbrough, 2 St. Helens, and 24·9 in Stockton-on-Tees.

The 5337 deaths from all causes in the 96 towns we fewer than the number in the previous week, and inc 402 which were referred to the principal epidemic dis against numbers declining from 464 to 410 in the preceding weeks. Of these 402 deaths, 215 resulted measles, 60 from whooping-cough, 53 from inf diarrhœal diseases, 35 from diphtheria, 23 from scarlet and 16 from enteric fever, but not one from small-pox. mean annual death-rate from these diseases last wee equal to 1·2, against 1·3 and 1·2 per 1000 in the two ceding weeks. The deaths attributed to measles, w had been 229, 220, and 208 in the three preceding w slightly rose to 215 last week, and caused the hi annual death-rates of 2·8 in Plymouth and in Smethwic in Wolverhampton, 3·5 in Bury, 3·9 in Walsall, 6 West Bromwich, and 7·3 in St. Helens. The d referred to whooping cough, which had been 83, 72, a in the three preceding weeks, further declined to 6 week, and included 16 in London, 6 in Stoke-on-Tren Bristol, 5 in Liverpool, and 3 in Warrington. The cases of diarrhœa and enteritis (among infants under 2 of age), which had been 69, 67, and 71 in the preceding weeks, fell to 53 last week; 17 deaths registered in London, 6 in Liverpool, 3 in Manch and 3 in Salford. The deaths attributed to dipht which had declined from 54 to 37 in the preceding weeks, further fell to 35 last week, and in 6 in London, 5 in Leeds, and 2 each in Willesden, on-Trent, Liverpool, St. Helens, Middlesbrough, Swansea. The deaths referred to scarlet fever, whic been 23, 28, and 19 in the three preceding weeks, w last week, of which number 5 occurred in London, Birmingham, and 2 in Manchester. The fatal cases of e fever, which had been 9, 13, and 8 in the three pre weeks, rose to 16 last week, and included 2 in London in Sheffield.

The number of scarlet fever patients under treatm the Metropolitan Asylums and the London Fever Ho which had steadily declined from 2112 to 1455 in the ceding weeks, had further fallen to 1410 on Saturda 167 new cases were admitted during the week, a 164, 156, and 168 in the three preceding weeks. hospitals also contained on Saturday last 900 ca diphtheria, 854 of measles, 282 of whooping-coug

39 of enteric fever, but not one of s
deaths from all causes in London wer
number in the previous week, and were equal to an annual death-rate of 16·3 per 1000. The deaths referred to diseases of the respiratory organs, which had steadily fallen from 453 to 380 in the five preceding weeks, further declined to 346 last week, but were 110 above the number recorded in the corresponding week of last year. The deaths *attributed to influenza last week numbered 45, against* 65 and 47 in the two preceding weeks.

Of the 5337 deaths from all causes in the 96 towns, 159 resulted from different forms of violence, and 402 were the subject of coroners' inquests. The causes of 27, or 0·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 60 other smaller towns. Of the 27 uncertified causes of death, 5 were registered in Birmingham, 3 in Liverpool, 3 in Warrington, 3 in Sheffield, and 2 each in Stoke-on-Trent, Preston, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1256 births and 744 deaths were registered during the week ended Saturday, April 5th. The annual rate of mortality in these towns, which had steadily declined from 20·7 to 17·2 per 1000 in the five preceding weeks, was again 17·2 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Scotch towns averaged 19·1, against a corresponding rate of 16·9 per 1000 in the 96 large English towns. Among the several towns the death-rates last week ranged from 9·1 in Kirkcaldy, 9·2 in Ayr, and 11·0 in Paisley, to 19·5 in Kilmarnock, 20·8 in Leith, and 24·8 in *Greenock.*

The 744 deaths from all causes were equal to the number in the previous week, and included 75 which were referred to the principal epidemic diseases, against 88 and 83 in the two preceding weeks. Of these 75 deaths, 43 resulted from whooping-cough, 13 from infantile diarrhœal diseases, 8 from measles, 6 from diphtheria, 3 from enteric fever, and 2 from scarlet fever, but not one from small-pox. These 75 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·7, against 1·2 per 1000 *in the 96 large English towns. The deaths attributed to* whooping-cough, which had been 50, 55, and 44 in the three preceding weeks, were 43 last week, and included 22 in Glasgow, 7 in Edinburgh, 5 in Leith, and 4 in Greenock. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis were 13 last week, against an average of 17 in the four preceding weeks; of this number 8 were recorded in Glasgow, 4 in Dundee, and 1 in Edinburgh. The fatal cases of measles, which had been 6, 5, and 9 in the three preceding weeks, were 8 last week, and included 4 in *Glasgow and 2 in Falkirk.* The 6 deaths attributed to diphtheria were equal to the average in the three preceding weeks, and comprised 3 in Glasgow and 3 in Dundee. The 3 deaths referred to enteric fever occurred in Glasgow, Edinburgh, and Greenock respectively; the 2 fatal cases of scarlet fever were recorded in Glasgow. In addition to the above diseases, 2 deaths from typhus fever were registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 144, 166, and 154 in the three preceding weeks, declined to 127 last week; 27 *deaths* were attributed to different forms of violence, against 25 and 17 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 746 births and 535 deaths were registered during the week ended Saturday, April 5th. The annual rate of mortality in these towns, which had been 23·4, 21·7, and 23·8 per 1000 in the three preceding weeks, declined to 23·3 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Irish towns averaged 22·2 per 1000; in the 96 large English towns the corresponding death-rate did not exceed 16·9, (against 16·3 in London and 18·7 in Glasgow), 21·2 in Belfast, 18·4 in Cork, 22·9 in Londonderry, 14·9 in Limerick, and 24·7 in Waterford, while in the remaining 21 smaller towns the mean death-rate was equal to 21·2 per 1000.

The 535 deaths from all causes in the 27 Irish towns were 12 fewer than the number in the previous week, and included 39 which were referred to the principal epidemic diseases, against 36 and 46 in the two preceding weeks. Of these 39 deaths, 14 resulted from measles, 11 from infantile diarrhœal diseases, 6 from diphtheria, 5 from whooping-cough, and 3 from scarlet fever, but not one from small-pox or from enteric fever. These 39 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; in the 96 large English towns the death-rate from these diseases last week did not exceed 1·2, while in the 16 Scotch towns it was equal to 1·7 per 1000. The deaths attributed to measles, which had been 13, 14, and 17 in the three preceding weeks, slightly declined to 14 last week, and included 4 in Newry, 4 in Wexford, and 2 each in Belfast, Cork, and Tralee. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 11, 7, and 8 in the three preceding weeks, rose to 11 last week, and comprised 7 in Dublin and 4 in Belfast. The 6 fatal cases of diphtheria, of which 4 occurred in Dublin and 2 in Belfast, were equal to the average in the three preceding weeks. The deaths attributed to whooping-cough, which had been 6, 4, and 10 in the three preceding weeks, declined to 5 last week, of which number 3 were registered in Waterford and 2 in Dublin. Of the 3 deaths referred to scarlet fever 2 were recorded in Belfast and 1 in Dublin. In addition to the above diseases a fatal case of typhus fever occurred in Dublin.

The deaths in the 27 Irish towns referred to diseases of the respiratory system, which had been 136, 138, and 122 in the three preceding weeks, rose to 142 in the week under notice. Of the 535 deaths from all causes, 169, or 32 per cent., occurred in public institutions, and 8 resulted from different forms of violence. The causes of 21, or 3·9 per cent., were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0 5 per cent

THE SERVICES.

NEW MEDICAL DIRECTOR-GENERAL OF THE NAVY.

Surgeon-General William May, C B., has been appointed Medical Director-General of the Navy, in succession to Surgeon-General Sir James Porter, K.C.B.

ROYAL NAVY MEDICAL SERVICE.

The following appointments have been notified:—Fleet-Surgeon: H. E. Tomlinson to the *Victory*, additional, for Portland Depôt, temporarily, on the *Imperieuse* paying off. Staff-Surgeons: A. S. Bradley to the *Excellent*, additional, for the *Dido*, on recommissioning; D. P. Chapman to the *Gibraltar*, additional, for the *Grafton*, on recommissioning; and W. P. Walker, to the *Gibraltar* for the *Crescent*. Surgeon: V. L. Matthews to the *Victory*, additional, for disposal, and to the Royal Marine Artillery Division, Eastney.

The Haslar Course for Acting Surgeons.

The Course for Acting Surgeons, Royal Navy, was brought to a close on March 28th at Haslar, when the prizes were distributed by Surgeon General Howard Todd. Special commendation was awarded to Acting Surgeons A. E. Malone, H. M. Whelan, and R. F. P. Cory for zeal and ability The gold medal was gained by Acting Surgeon Malone (Dublin University), who obtained the highest aggregate marks in the London, Greenwich, a [illegible] silver medal by Acting S [illegible] Cardiff, and the London [illegible] The grou [illegible] at Green [illegible] and the [illegible] awarded in Group I. to Acting Surgeon Whelan, and in Group II. to Acting Surgeon Cory (St. Thomas's Hospital)

The order of seniority, as determined by the results of the examinations held at London, Greenwich, and Haslar, is given below:—

	Marks.
1. A. E. Malono, M.B. ...	3664
2. H. M. Wholan	3502
3. R. F. P. Cory	3467
4. H. St. C. Colson	3371
5. G. A. Finogan...	3069
6. J. T. D. Higgins, M.B.	3872
7. J. G. Boal, M.B.	3860
8. F. S. B. Wickham... ...	3845
9. S. Punch	3833

ROYAL ARMY MEDICAL CORPS.

Colonel C. E. Faunce has taken up duty as Assistant Director of Medical Services to the Woolwich District and in charge of the Royal Herbert Hospital, in succession to Colonel R. W. Ford, D.S.O., who has been placed on the half-pay list.

Lieutenant-Colonel J. B. Wilson has been selected for the increased rate of pay under Article 317 of the Royal Warrant for Pay and Promotion. Lieutenant-Colonel S. Macdonald has taken up duty as Medical Inspector of Recruits to the Southern Command at Headquarters, Salisbury. Lieutenant-Colonel A. W. Bewley has been selected for appointment as Deputy-Assistant Director of Medical Services to the Northern Command at York, in succession to Lieutenant-Colonel F. R. Newland, appointed to hold charge of the Military Hospital at Dover. Lieutenant-Colonel C. Cooper-Reilly has been transferred from the Belgaum Cantonment to Colaba, Bombay.

Major E. W. W. Cochrane has arrived home for duty from Bermuda. Major G. T. K. Maurice has been transferred from the Military Hospital at Reading to the Military Hospital at Tidworth, Salisbury Plain. Major M. P. Corkery has been appointed to the Military Hospital at Fermoy. Major T. B. Unwin has left the London District for a tour of service in the Sierra Leone Protectorate. Major A. L. A. Webb has been appointed for duty in the Scottish Command. Major R. W. H. Jackson has been selected to hold charge of the Military Hospital at Weymouth. Major E. McDonnell has arrived home for duty from Bermuda. Major F. M. Mangin has embarked for a tour of service in India. Major T. E. Fielding has been appointed to the Southern Command. Major W. G. Beyts has been granted three months' general leave of absence from India. Major J. F. M. Kelly has been appointed to the Eastern Command. Major A. H. N. Mitchell has been transferred from Netley to the Eastern Command.

Captain A. W. Bevis has been appointed to the Belfast District for duty. Captain W. B. Purdon has taken up duty at the Military Hospital, Devonport. Captain C. J. W. Wyatt has been placed under orders for a tour of service in the Sierra Leone Protectorate. Captain A. Dawson has been appointed to the Dublin District for duty. Captain F. A. H. Clarke has left Glasgow for a tour of service in India. Captain J. B. Meldon has been transferred from the Military Hospital at Dover to Brighton. Captain W. C. Smales has taken up duty at the Military Hospital, Portsmouth. Captain P. Sampson has been appointed to the Irish Command. Captain J. W. Houston has been transferred from the Military Hospital at Colaba to the First (Peshawar) Division of the Northern Army in India.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of the undermentioned officers of the Indian Medical Service:—

Lieutenant - Colonel John Macfarlane Cadell (dated March 5th, 1913). Lieutenant-Colonel Charles Hardwick Louw Meyer (dated March 15th, 1913). Major Thomas Edgar Watson (dated March 15th, 1913).

Lieutenant-Colonel G. T. Birdwood has been selected for appointment as Professor of Pathology on the staff of the King George Medical College at Lucknow. Lieutenant-Colonel W. Molesworth has been granted one year's combined leave of absence home from India. Lieutenant-Colonel H. Austin Smith, civil surgeon, Simla East, has been appointed to hold officiating Medical Charge of Army Headquarters Staff and Establishment.

Major P. Dee has been appointed to officiate as a First-class Civil Surgeon under the orders of the Government of Burma, in succession to Major E. R. Rost, granted leave of absence. Major J. N. Walker has been selected for appointment as Civil Surgeon at Aligarh. Major E. L. Perry has been granted privilege leave for three months combined with four months' study leave home from India. Major C. C. S. Barry has been selected as Superintendent of the General Hospital at Rangoon, in succession to Major T. Stoddart, transferred to Mogok. Major A. M. Fleming has taken up duty at Jubbulpore, in succession to Captain J. M. A. Macmillan, appointed Civil Surgeon at Amraoti. Major T. E. Watson has arrived home on leave of absence from India.

Captain M. A. Nicholson has been selected for appointment as Medical Officer in charge of the Lawrence Military Asylum at Sanawar, in succession to Captain J. Simpson. Captain S. C. Pal has been selected for appointment as substantive Medical Officer to the 108th Native Infantry Regiment stationed at Bangalore, in succession to Major W. H. Cox, D.S.O. Captain J. S. O'Neill has been appointed to officiate as Civil Surgeon at Jhansi. Captain A. N. Dickson has arrived home on leave of absence from India. The services of Captain H. H. G. Knapp have been placed permanently at the disposal of the Government of Burma for employment in the Jail Department. Captain A. Cameron has been selected for appointment as Chief Plague Medical Officer in the United Provinces of Agra and Oudh, in succession to Lieutenant-Colonel H. B. Melville. Captain G. J. Davys has been appointed Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Brigade Headquarters, Jubbulpore. Captain C. H. Barber has relinquished medical charge of the Banda District. Captain C. Rigby Lynn has been transferred from Trichinopoly to Delhi and appointed Medical Officer to the 11th Lancers. Captain A. McD. Dick has been appointed a Specialist in Advanced Operative Surgery. Captain A. J. V. Betts has returned to India from leave of absence home. Captain E. A. Walker, officiating ophthalmic surgeon at the General Hospital, Rangoon, has been appointed to officiate as Civil Surgeon at Bassein, in succession to Lieutenant-Colonel J. Penny. Captain J. Anderson has been selected for appointment as Civil Surgeon at Hazara. Captain J. Taylor has been granted three months' privilege leave combined with six months' study leave home from India.

Lieutenant R. A. Murphy has taken up duty as Medical Officer to the Surma Valley Light Horse.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Mark Anthony resigns his commission (dated April 2nd, 1913). Lieutenant Alexander D. d'Avray is confirmed in his rank. Cadet Harry Chapman Sinderson, from the Edinburgh University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated March 6th, 1913). Harry Evans, late Cadet, Edinburgh University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Feb. 15th, 1913). Cadet Staff Sergeant Walter Tennyson McCurry, from the Belfast University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated March 11th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Lancashire Field Ambulance, Royal Army Medical Corps: Major Wilfred M. Steinthal to be Lieutenant-Colonel (dated March 1st, 1913).

Supernumerary for service with the Officers Training Corps: Lieutenant George A. Williamson is appointed to serve with the Aberdeen University Contingent, Senior Division, Officers Training Corps (dated July 13th, 1912).

Attached to Units other than Medical Units.—Lieutenant Arthur H. Norris to be Captain (dated Dec. 21st, 1912).

Sanitary Service.—Lieutenant James Dundas, from the 2nd Home Counties Field Ambulance, Royal Army Medical Corps, to be Captain, whose services will be available on mobilisation (dated April 9th, 1913).

ROYAL ARMY MEDICAL CORPS EXAMINATION.

An examination for commissions in the Royal Army Medical Corps (probably not more than five) will be held on July 23rd. Applications to compete should be made to the Secretary, War Office, not later than July 14th.

COLONIAL MEDICAL SERVICES.

West African Medical Staff.—Dr. A. W. Atkinson, medical officer, Gold Coast, has retired with a gratuity, and Dr. St. G. Gray, senior medical officer, Southern Nigeria, has retired on a pension. The following gentlemen have been selected for appointment to the staff: Mr. N. A. D. Sharp (Gold Coast), Dr. J. C. O Hogan (Northern Nigeria), and Dr. J. A. Beattie (Northern Nigeria).

Correspondence.

"Audi alteram partem"

MEDICAL OFFICERS OF HEALTH (SUPERANNUATION) BILL: AN APPEAL TO SCHOOL MEDICAL INSPECTORS AND TUBERCULOSIS OFFICERS

To the Editor of THE LANCET

SIR,—In the House of Commons on April 18th there is set down for the second reading the Medical Officers of Health (Superannuation) Bill Medical officers of health, whether whole time or part-time, are included in the provisions of the Bill, which is on a contributory basis

A memorandum on the Bill is contained in the April number of *Public Health*, which sets out the strong claims for superannuation of medical officers of health Medical officers of health are now generally recruited from the ranks of the junior branches of this service—namely, school medical inspectors and tuberculosis officers, of whom there are at present at least three times as many as of medical officers of health This means that there will always be the larger proportion of officers remaining in these junior branches of the service which are paid at a rate of salary ranging from a half to a third of that paid to whole time medical officers of health

Since the Insurance Act came into operation school medical inspectors are, outside institutions, the lowest paid members of the profession All the arguments in the Bill *can be urged in the case of medical* inspectors and tuberculosis officers, and the argument contained in the following extract from the memorandum on the Bill can be much more powerfully supported in favour of the junior services

> Moreover they (medical officers of health) can hardly be classed among highly paid officials and have thus little opportunity for saving sufficient from their incomes to enable them to retire when it might be distinctly in the public interest to do so

My object in writing is to point out that the Bill does not include school medical inspectors or tuberculosis officers and to have an amendment brought forward, and, if possible, incorporated in the Bill during the Committee stage to make the words "medical officers of health" include school medical inspectors and tuberculosis officers To this end may I ask all school medical inspectors and tuberculosis officers to write to me without delay, saying whether they are in favour of such a course, and to write or interview their Member of Parliament urging him to assist the progress of the Bill safely through Parliament

I am, Sir, yours faithfully,
ALEXANDER GRAHAM,
School Medical Inspector
West Ham, April 7th, 1913

PROFESSOR BIEDL'S TREATISE ON "THE INTERNAL SECRETORY ORGANS"

To the Editor of THE LANCET

SIR,—Although I consider any controversy with Dr Leonard Williams in reference to the English translation of my work, "The Internal Secretory Organs," futile and to be deprecated, his letter in THE LANCET of March 29th calls for some remark and constrains me to reply With your permission I also desire to recapitulate the inner history of the translation and to explain my part in the origin of the strictures referred to by your reviewer

In my contract with the London publisher I stipulated in the first place that the translation was to be made by a competent expert, and further that I was to be allowed to supervise and to correct it as far as was necessary I was informed by the publisher that Dr Leonard Williams would undertake the responsibility of the *translation, and I was not a little* astonished to find on the publication of the book Miss Linda Forster as translator I was, moreover, disagreeably surprised that the preface in the original from the pen of Professor Richard Paltauf, of Vienna, had been suppressed and replaced by a foreword from Dr Leonard Williams without my first being referred to I am convinced that the original preface would have been of greater interest to the English reader

In the typewritten manuscript which was submitted to me in parts—often after a considerable interval of time—I found various inaccuracies, names of authorities wrongly spelt and mistakes of more essential importance due to an imperfect understanding of the original text all requiring correction I considered it my duty to correct these in detail To these corrections, for example, it is due that the names of the authors in the English version are more correctly given than in the original I would not have corrected inaccuracies in the language had my attention not been drawn to them by a thoroughly competent man, Dr C Lawrence Herman, of Capetown, who undertook the weary and thankless task of revising and correcting the manuscript

With due deference to Dr Leonard Williams, I maintain that these corrections in the majority of instances have been incorporated with great advantage to the translation If the English version "as a whole is well done and gives very fairly the spirit of the original," this is undoubtedly due in some measure to my friend Dr Herman The remarks of Dr Williams in reference to my "professorial style" and my "knowledge of the English language" are unnecessary and uncalled for, while his desire to saddle me with the responsibility for "some Germanicisms and curious renderings" is unjust If it amuses Dr Williams to make fun of my corrections "auf echteste und korrckteste pädagogische Weise," I can only assure him that the revision and correction of the manuscript were undertaken in the most loyal and friendly spirit of cooperation, with the sole desire of making the English version worthy of being read by all interested in the subject in England and elsewhere Moreover, I am not without hope that Dr Williams, on more mature consideration, will come to see that his remarks were ill judged and little befitting the occasion

The just strictures of your reviewer in his sympathetic and courteous remarks are sufficient evidence that it would have been better had the printer's proofs been sent to me as well for final correction, in which case such errors as "jodothyrin in suprarenals," "gall" instead of bile, "secretary" instead of secretory, "intercranial pressure" for intracranial, would not have escaped me

Unusual as it may be that an author reserves to himself the right of correcting and amending the translation of his work in a foreign language, the desire of Dr Leonard Williams to place to my credit any deficiencies in the English translation makes it clear to me that in this instance at least I have not sufficiently safeguarded myself in all directions Thanking you in anticipation for the publication,

I am, Sir, yours faithfully,
Prof BIEDL
Wien, April 1st, 1913

SOME POINTS IN SURGICAL TECHNIQUE.

To the Editor of THE LANCET

SIR —A simple and efficacious plan has occurred to me for ensuring a completely skin covered, and therefore skin-free, wound during operation, whereby one potent source—the *patient's skin—of wound contamination might be obviated* As I feel sure it will prove of value and commend itself to others I will describe it It is carried out either by the aid of suture or Michel's clips Directly the skin incision is made and before the operation is further proceeded with, on both sides of the wound the margins of the sterile covering are tucked round the skin margins so as to hide completely the skin from view and fixed in this position till the end of the operation If a suture be used a continuous or interrupted one is passed through covering, skin, and covering in the order named, whilst if the clips be exploited they are clamped to the skin margins by penetrating the two layers of covering At the extremities of the wound two clips are applied so as to keep together the two margins of the covering By this simple, facile, and speedy process the skin is covered and *is not seen or touched during the operation* (to my mind, a most important, although usually neglected, precaution) Thus, the sterile cloth is carried round the skin margins on to the subcutaneous tissue, on the one hand, and in the other direction covers the skin in the neighbourhood in the ordinary way, and hence it will be seen that the sterile cloth is continuous with the germ free subcutaneous tissue, and as far as the patient is concerned we have a sterile field and wound. I strongly commend this simple expedient. I have elsewhere described some towel clips constructed to my requisition by Messrs. Mayer, Meltzer, and Co., one of the chief objects of which was to bring about the same result.

Bearing also on the subject of primary union of wounds, I would like to call attention to a plan adopted recently on my own initiative in regard to the question of operative skin preparation and treatment. This method is based upon the phenomenon, which I think cannot be denied, that all clean wounds heal much better if kept dry, and that moisture undoubtedly favours or provokes inflammation. No one would think of applying a moist dressing to, or keeping wet, a clean wound if healing by first intention were desired, for such an action would court disaster. To operate on a sodden skin would be folly, and I think a good deal of the trouble experienced with wounds, even after the most careful preparation, is due to previous humidity; and to my mind there is no more culpable *agent provocateur* than the favoured and time-honoured protective compress. Probably much of the failure in, and past difficulty in explaining the state of, operative wounds finds its elucidation here. This old and favourite method might be called the wet compress method (lint, protective and wool) as opposed to the one to be described—namely, the dry compress method. I believe much of the value and credit gained by iodine applications to be due not only or necessarily to its hyperæmic and bactericidal properties, but also to the desiccating properties of this preparation. Water being a *sine quâ non* for the life of vital organisms, and therefore of bacteria, and dryness spelling death or quiescence, it would appear that the day of moist applications is over, and that no compress or dressing that includes protective (moisture retaining) should henceforward be considered. Pathological knowledge and surgical experience condemn such. The dry method is as follows. The skin is washed by ether soap (never scrubbed), then gone over with turpentine, followed by spirit of biniodide of mercury. Now come the chief modifications. The skin is covered by sterilised talcum toilet powder; any of these may be used, as the preparations of Parke Davis, Colgate, Sewar, &c. These powders are free from irritating antiseptics, and have valuable desiccating properties. The powder is now gently rubbed into the skin by a sterile piece of wool, after which the part is covered by a thick layer of powder, and the whole region covered by a dry sterile compress, which is bandaged on, but mind, no protective of any kind to keep the skin sodden or retain moisture, and therefore invite bacterial activity and disaster. At the time of operation the skin presents an ideal appearance, for it is dry, and, I think, as a fact and for this reason gives gratifying results; at least, such has been my experience so far. At the end of the operation the line of incision is covered with a thick layer of powder; incidentally this prevents adhesion of wound to dressings, and thereby obviates this source of irritation to the patient as well as to the wound. On subsequent days powder is applied again as required. I have noticed during the adoption of this technique not only absence of redness at the site of incision but also at the sites of the suture punctures. Perhaps a combination of this powder method and iodine might give even better results. But so far I am satisfied.

I would, therefore, lay emphasis on the dry method of preparing the skin, the avoidance of anything that will render moistness inevitable, especially the old and bad protective (oiled silk, gutta-percha tissue, &c.) compress application. The results so far obtained promise well for the future and are most encouraging.

I am, Sir, yours faithfully,
G. S. THOMPSON, F.R.C.S. Eng.
Kimberley, S. Africa, March 10th, 1913.

A DANGER TO HEALTH IN THE NEW FOREST.

To the Editor of THE LANCET.

SIR,—My attention has been called to an article with the above title which appeared in THE LANCET of March 29th, p. 910, that does grave injustice to the work of the medical officer of health for Ringwood, Mr. Charles E. Blackstone, and also to that of the medical officer of health for the county, Dr. Robert A. Lyster, and to the rural district council. Anyone reading your remarks would conclude that a plague spot, indeed, has been discovered, and that it was administered by a most careless local authority, assisted by thoroughly incompetent officials.

The report of the medical inspector of the Local Government Board, Dr. H. A. Macewen, upon which your remarks are based, is an unfortunate and misleading one, and contains many apparent errors in the statement of facts, concerning which it is difficult to understand how mistakes could arise. As, however, correspondence is going on between the Ringwood district council and the Local Government Board upon this report, I will not attempt to dealt with that matter here, but will instead briefly state what actually occurred. Before doing so I may as well freely admit that the water-supply of Ringwood is derived from shallow wells. As the result of examinations from time to time by successive medical officers of health these wells have not been unfavourably reported on, and the district council have given special attention to endeavour to preserve them from surface pollution. There has been nothing in the vital statistics of the district to cause concern, and though a public water-supply is probably an advantage, provided that it is derived from absolutely reliable sources, yet there have been no signs until recently that the ratepayers would sanction such a course.

Coming now to the epidemic of enteric fever last year, the first notifications reached the medical officer of health on August 13th, the cases then being of a mild type, and, I believe, entirely confined to children. The earliest case of the commencement of illness discovered here was on July 26th. We can find no trace of a case on July 18th, as mentioned by you. At all events, no case was notified until August 13th, no doubt because the disease could not be clearly diagnosed before then. On August 19th the district council met, and first heard of the outbreak. They consulted with their medical officer of health and with Dr. J. Gott, Poor-law medical officer, and upon their advice decided to at once engage nurses to work amongst the patients at their homes. The question of an isolation hospital was discussed, but temporarily allowed to remain in abeyance, as doubt was expressed as to the parents consenting to the removal of their children. It was arranged, however, that the health committee of the district council should be strengthened, and be summoned directly the epidemic showed signs of increasing. This committee met on August 21st and many times afterwards, and at once decided to open an isolation hospital, which was done on August 27th, or eight days after the council first heard of the outbreak, and 14 days after the receipt of the first notification. You refer to this hospital as being "of an unsatisfactory kind." It consisted of a fair-sized farmhouse in an open situation, with lofty rooms. A large Doecker hut was added as an annexe and a day room for convalescents was built of wood and galvanised iron in addition. It is a matter of opinion, of course, but most competent judges thought the hospital accommodation fairly good and decidedly creditable under the circumstances. On August 29th a letter was received by the clerk to the district council from the Local Government Board asking that the former body would request their medical officer to submit a report upon the epidemic. The next meeting of the council took place on Sept. 2nd, when this letter came before them and was dealt with. But on August 31st, late at night, Dr. Macewen appeared upon the scene, full of surprise that the desired report had not been received. He called upon the medical officer of health, who, late though it was, was extremely busy, and expressed his views in such language that a speedy termination of the interview was brought about. He also called on the chairman, the vicar of the parish, who no doubt received him with every attention, but as a clergyman with a heavy Sunday's duty before him the next day could hardly be expected to unduly prolong the conversation.

As to the cause of the epidemic, directly its presence was made clear every step was taken to try and establish from whence it originated. Water, milk, school contact, and so on, were all investigated in turn, Dr. Lyster, county medical officer of health, rendering th[illegible] the endeavours that were made. In [illegible] had been in conference with Mr. Blackstone on August 31st and had borrowed the written data for consideration until Sept. 2nd, when he returned it. This was the reason why this data was not available for Dr. Macewen's perusal on the evening of the same day, as he perfectly well knew. Although Dr. Lyster returned the papers on Monday, Sept. 2nd, it seems singular, but it is a fact, that Dr. Macewen never again asked to see them. It is also the case that he never once interviewed the district council, though they would have been pleased to see him. He casually met two members by chance, of whom I was one, and had a few words of conversation of quite an unofficial character, and, as already stated, he called upon the chairman. Dr. Macewen has expressed the opinion that the cause of the epidemic was the stream you allude to. I have been through his evidence most carefully, comparing it with reliable data, and as far as I am able to judge his theory and his evidence tumble to pieces when tested. In reports submitted to the district council, Mr. Blackstone states that, though the matter is not free from doubt, he believes that the strongest evidence points to the epidemic having originated from ice-cream supplied at school treats, the subsequent cases being contacts, and the ice-cream maker an intermittent carrier. I understand that Dr. Lyster also favours this view, though investigations are still going on in connexion with it.

I hope in justice to two capable and most assiduous medical men, if not to the district council, you will take steps to correct the most unfortunate impression conveyed to anyone reading your article who was ignorant of the real facts of the case.—I am, Sir, yours faithfully,

HOWARD TOZER,
Vice-chairman, Ringwood Rural District Council.
Ringwood, April 6th, 1913.

QUIS CUSTODIET IPSOS CUSTODES?

To the Editor of THE LANCET.

SIR,—A few days ago I sent a patient with somewhat obscure symptoms to have his blood examined at a well-known clinical laboratory in London, and received back a report which strongly suggested that he was suffering from an early stage of pernicious anæmia. In view of the importance of the matter I decided, before starting him on a course of arsenic, to obtain further corroboration of the diagnosis, and accordingly sent him to another laboratory in London for a second blood examination. A report followed which entirely negatived the diagnosis of pernicious anæmia. Only three days elapsed between the two examinations; during that time there was no alteration in the patient's symptoms and he had no special treatment. In each case the blood was taken at the laboratory, and at about the same hour of the day. I append the chief points in the two reports. It is upon facts such as these that the unfortunate physician has nowadays largely to rely for his diagnosis and his treatment. I need only add that I had a third examination made with the greatest care by a hospital colleague, and the results obtained differed materially from those given in both the previous reports, though they approximated more nearly to those in the first..

	Report 1.	Report 2.
Hæmoglobin	75 per cent.	84 per cent.
Red corpuscles	2,900,000 per c mm.	5,485,000 per c.mm.
White corpuscles ...	5,000 „	9,000 „
Colour index	1·3	0·8
Poikilocytosis	Moderate.	Absent.
Differential count—		
Polymorphonuclears	67·0 per cent.	57·0 per cent.
Small lymphocytes	28·5 „	30·0 „
Large lymphocytes	2·5 „	7·3 „
Eosinophiles	1·5 „	5·7 „
Mast cells	0·5 „	

I am, Sir, *yours faithfully*,
Cavendish-place, W., April 5th, 1913. J. WALTER CARR.

RECOVERY IN ACUTE TUBERCULOUS PNEUMONIA.

To the Editor of THE LANCET.

SIR,—I read with some interest Dr. S. N. Galbraith's paper on "Acute Tuberculous Pneumonia: Recovery" in to-day's issue of THE LANCET. I am of opinion that such cases are far from uncommon, though I would suggest that the prognosis is never really good.

The following is a good example of this condition. The patient, a youth 16 years of age, was admitted to the Ayrshire Sanatorium on August 16th, 1910. His illness commenced 16 weeks before admission and followed directly on over-exertion, produced by a long bicycle ride; he was, however, walking two or three miles every day until his admission to the sanatorium, though unable to follow his occupation of coalminer; during this period he was suffering from heavy night sweats. On admission he was running a temperature varying from 101°F. at night to 99° in the morning, which fell to normal in eight days following upon rest in bed and silence, and after that was never above the normal, his rectal temperature before rising averaging 97·7°. He had four ounces of sputum on admission containing tubercle bacilli. Physical examination revealed a condition of massive consolidation, apparently involving the whole of the left lung; there were also signs of softening at the right apex. He remained in the sanatorium five months, during which time he was able to do fairly heavy work in the garden, such as digging and wheeling barrows, without producing symptoms of auto-inoculation; he gained 19½ lb. in weight, and looked and felt quite well. His sputum was reduced to two or three pieces, and bacilli were not found when last examined. The condition at the left side of the chest was practically unchanged; the lung was apparently quite solid from apex to base. He returned home on Jan. 13th, 1911, and worked in a factory until April, 1912. His lung, I believe, then broke down, and he died on June 5th, 1912.

The following is another example. The patient, a young man 20 years of age, was admitted on Sept. 9th, 1912, and discharged on Nov. 1st. The commencement was somewhat different from that in the last case. He described himself as having been quite well until April, 1912; just before this he had complained of a little cough and some weariness. He then went home for a week-end, and owing to the coal strike was compelled to walk eight miles; at the end of this walk he was completely done, and his mother informed me that when he reached home he looked like a corpse. He became delirious after the walk, and remembered nothing for a month; he was thought to have acute pneumonia, and had consolidation of the whole of the right lung. At the end of a month he began to improve, and was sent to the sanatorium some months later. On admission he was afebrile, the pulse was usually over 100, and respirations 24; his breath was rather short. His temperature remained normal until he had a dose of Spengler's I.K., 0·2 c.c of 1 in 100,000, which immediately sent it up and increased his sputum and made him generally ill. The temperature fell immediately after another dose of 0·2 c.c. of 1 in 10,000,000. He then went home. On leaving, the right side of the chest was still quite solid. The sputum on admission and on discharge contained abundant tubercle bacilli. I saw his medical adviser three days ago, and he tells me that the patient is improving and that his pulse has dropped to 96.

I have at present in the sanatorium two similar cases. One of them is interesting from the retrospective standpoint, for in his case the pneumonic consolidation occurred ten years ago. At that time he was in bed three months and was off school 14 months. Since then he remained well until November, 1912, when he had a fresh outbreak. He was only admitted to the sanatorium on March 28th last, and his condition is quite good. The upper lobe on the left side shows extensive consolidation. Like the majority of these cases, he has very little sputum, but what there is is loaded with tubercle bacilli. As he has had a cough ever since his first attack, he would seem to have been very dangerous to his neighbours.

With regard to the above examples I should like to point out that both the two severe cases resulted from over-exertion in the early stage of pulmonary tuberculosis; secondly, that it was probably the massiveness of the consolidation which put a period to the acute symptoms, the massive consolidation greatly limiting movement, and at the same time greatly reducing the blood-supply. Furthermore, I am inclined to think that it is the massiveness of the consolidation which is the ultimate undoing of such cases. From experience I am led to believe that consolidation is the most difficult condition to cure of all the complications of phthisis, its seriousness depending on its extent. Where massive, tuberculin is unlikely to be of great benefit, though if given carelessly may well produce such a condition, for any immunity acquired by the administration of tuberculin is of necessity transitory, and efforts to break down and cause exfoliation of these masses are liable to produce calamitous results.

Personally, to me there seems [illegible] for giving diagnostic injections of old tuberculin, for in any case a focal reaction, though it may indicate active disease, by no means indicates that the disease was active until the tuberculin was administered, and because a focal reaction is not discernible it does not follow that the patient is therefore well. This is well shown in the second case mentioned by Dr. Galbraith. Doubtful cases may either be treated on general lines or tuberculin administered, commencing with small doses and gradually increased. It is, of course, well to remember that solid lung may be due to the pneumococcus and may clear up after appropriate vaccine treatment.

I can confirm what Dr. Galbraith says about the value of whispering pectoriloquy in this condition; all the above cases exhibited this in a marked manner. In addition, both these bad cases had a peculiarly unwholesome smell which remained as long as they were under observation.

I am, Sir, yours faithfully,
Edward E. Prest.

Ayrshire Sanatorium, New Cumnock, April 5th, 1913.

INSANITY AND DIVORCE.

To the Editor of The Lancet.

Sir,—With reference to the proposal that after a certain number of years' detention in an asylum insanity should form a plea for divorce, I would like to draw attention to a case in which recovery took place after 17 years' continuous residence.

A lady, aged 42, admitted March, 1896. Weight 7 st. Was in a condition of complete mental stupor, refusing to speak, eat, or make voluntary motion of any kind; catheter required to be passed, and bowels washed out by enemata. In May began to take food by herself; bowels and bladder acted normally. She was able to be up, but sat all day like a log, and was passively resistive.

In August underwent a course of thyroid treatment, but till October showed little or no change. She then began to improve in bodily health, though continuing dirty in her habits and persistently silent. At the end of 1898 had passed her climacteric; by this time she occasionally spoke a little, and she became much more correct in her habits. During the following ten years she slowly improved bodily and mentally, speaking freely, though in a somewhat childish manner, was able to do a little housework, sewing, &c., and by 1909 was to all appearances a typical case of mild terminative dementia. Weight 15 st. From this time, however, marked mental improvement took place. She gradually became active in mind and body, taking a keen interest in her own and outside affairs, and she was discharged recovered in March of this year.

I cannot see why insanity (unless wilfully concealed) should be pilloried as a plea for divorce more than any other illness, which is not directly due to evil living.

I am, Sir, yours faithfully,
J. Batty Tuke, Jnr., M.D., F.R.C.P. Edin.

Polton, Midlothian, April 7th, 1913.

IODOFORM INJECTIONS IN PULMONARY TUBERCULOSIS.

To the Editor of The Lancet.

Sir,—Some one has remarked that if all the remedies for tuberculosis were effectual it is difficult to understand why any person should die from it. Pending the establishment of a scientific basis for the therapeutics of this disease, I may, perhaps, be permitted to submit the results of my experience in six pulmonary cases treated by intravenous injections of iodoform. Of these cases one was acute, two advanced, and the remaining three early.

Of the advanced cases one died from intercurrent causes, the pulmonary symptoms having been considerably ameliorated. This case showed improvement in the physical signs in proportion to the dose and frequency of the iodoform administered. The acute case has, after 15 months' treatment, reached a condition of convalescence, tubercle bacilli are no longer to be found in the sputum, and there are no physical signs in the lungs. The remaining four cases show a regularly progressive improvement, and, in my opinion, are doing better than they would do under any other treatment that I know.

I am also using iodoform injections in a case of fœtid bronchitis in a man of 30, who before treatment expectorated daily about 10 oz. of stinking pus. After six weeks' treatment his expectoration has diminished by half, is clearer in colour, and free from smell.

I am, Sir, yours faithfully,
E. Curtin.

Bournemouth, March 25th, 1913.

THE WORKING OF THE NATIONAL INSURANCE ACT.

To the Editor of The Lancet.

Sir,—The importance at the present stage of National Insurance to the medical profession of settling the question of certification, alluded to in a leading article last week, heard before Mr. Justice Bailhache, is obvious. Instances can easily be imagined in which the point would arise. Counsel for the plaintiff, in the case on which the article was founded, suggested the example of a domestic servant in the house of an eminent physician who might well not be on the panel but who, equally reasonably, might be expected to attend his servant, and would certainly be medically qualified to give a certificate stating her incapacity and fitness for sick pay. There would also, no doubt, be cases which would tell the other way; for example, a medical man may be removed from a panel under Section 15, Subsection 2 B, of the Act, and no doubt the possibility of a sick insured person tendering the certificate of such a practitioner must be taken into consideration. Section 67 orders that "every dispute between an approved society, or a branch thereof, and an insured person who is a member of such society or branch relating to anything done or omitted by such person, society, or branch (as the case may be), under Part I. of the Act or any regulation made thereunder shall be decided in accordance with the rules of the society, but any party to any such dispute may in such cases and in such manner as may be prescribed appeal from such decision to the Insurance Commissioners." The Insurance Commissioners are, it may be noted, empowered to authorise referees to hear appeals or disputes submitted to them under this section, and there need be no delay in settling the case now at issue.

I am, Sir, yours faithfully,
Medico-Legal.

April 7th, 1913.

THE POSITION OF ASSISTANT MEDICAL OFFICERS IN ASYLUMS.

To the Editor of The Lancet.

Sir,—At the present time, owing to a dearth of suitable candidates for the posts of assistant medical officers in asylums, statements have been widely circulated that a term spent in that capacity forms one of the best experiences a man intending to enter general practice can have. It is true than men spending a short time in this way have succeeded conspicuously in other walks of the profession, but I think it is probably not because of this experience but in spite of it. Before taking this step a newly qualified man would be well advised to inquire into the conditions of the service. He will find that he is practically cut off from all surgical work, and to all intents and purposes from medical work of any importance perhaps for years. In nearly all asylums even a minor operation requiring an anæsthetic is performed by an outside surgeon specially employed. In all large asylums the junior man is given medical charge of patients that practically call for no medical attention whatever—viz., the demented class; and when one of these becomes so indisposed as to require medical attention to any extent the senior assistants take the case out of his hands into the infirmary. Even here a great lack of medical atmosphere is apparent as in few asylum infirmaries is there any trained nursing as ordinarily understood, attention being largely concentrated on cleanliness, feeding, and the prevention of injuries, all very necessary in their way, but falling far short of the keen clinician's ideas for the treatment of the sick. The junior assistant will find a great part of his time taken up with purely routine visits to his wards, writing more or less formal notes about the uneventful lives of dements, and endeavouring to get through a much too abundant monotonous and irksome leisure with such games as may be at hand, or at best a very uninspiring dalliance with a microscope. The fact is that men should only enter the service, not as a training for wholly dissimilar work such as general practice, but with a view to making asylum work their career, and steps ought to be taken by the authorities to make it such. The large number of assistant medical officers in asylums with the extremely infrequent vacancies for superintendents leaves many an otherwise excellent medical man stranded, having had a training and environment for years almost completely out of sympathy with the rest of the profession and therefore greatly handicapped in taking his stand beside them if he gives up asylum work. *Initial salaries should have little weight with intending* candidates as subsequent advancement under present conditions is most uncertain, and indeed often a matter of luck.

I am, Sir, yours faithfully,

April 7th, 1913. REFORM.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. Jordan Lloyd.

THE death of Mr. Jordan Lloyd, joint professor of surgery in the University, senior surgeon to the Queen's Hospital and one of the best-known exponents of his science and art in our city, has been a source of real regret in all circles.

Hospital Saturday Fund.

The annual report states that the total receipts for last year amounted to £22,842 2*s.* 4*d.*—viz., £22,610 2*s.* 1*d.* collected in factories and other establishments and £232 0*s.* 3*d.* interest allowed by bankers. This total is £901 19*s.* 6*d.* in excess of the previous year's collection and *constitutes another record.* The number of contributing firms was 2190, a decrease of 34. £10,000 were voted for distribution among the medical institutions of the city towards the cost of their free work. At the convalescent home for men, Tyn-y-Coed, near Llandudno, 1245 patients were admitted, and at the women's convalescent home, Marle Hall, near Llandudno, 1446 patients were admitted. 632 children and 106 women entered the Red House, Great Barr. The total number of patients dealt with was 3429 Since the Fund's first convalescent home was established, 21 years ago, 44,770 patients have been received. The benefit that in this way has accrued, not only to the subscribers, but to the city at large, is incalculable. Through the surgical aid department 904 articles were supplied during the year. Through this department patients can obtain reliable articles at minimum prices and can pay for them by instalments. Rheumatic patients have been sent to St. John's Brine Baths Hospital at Droitwich. The Cook Memorial Sanatorium for Consumptives, erected by the Fund, will be opened during this summer, and part of the building will very shortly be available for men. The coming into force of the Insurance Act [illegible] part [illegible] reco[illegible] tions under the Act should interfere with the Hospital Saturday Fund, as the benefits offered are quite distinct. In nearly all cases where collections were temporarily suspended they have already been recommenced.

The Birmingham Insurance Committee.

The Local Medical Committee has now been approved by the Insurance Commissioners, and the Local Insurance Committee has been completed by the election of the medical members. Since the Act came into force 1036 completed applications for sanatorium benefit were received up to March 14th, and the expenditure amounted to £6404 17*s.* Of the 1036 applicants, 930 have been examined and 775 passed for treatment. There has been great difficulty with regard to sanatorium accommodation, but circumstances will be altered when the city sanatorium at Yardley-road is completed. Thirty beds will be available this month at Romsley Hill Sanatorium, and in six months' time 100 beds. The results of treatment appear to be satisfactory, in most cases [illegible] ommittee. About 80 patients have been treated in their omes. A small subcommittee has been appointed to make rrangements for the provision of domiciliary treatment, the supply of drugs, and for tuberculin required by general practitioners.

Birmingham and Midland Skin and Urinary Hospital.

According to the annual report, 276 in-patients were treated last year as compared with 185 the previous year; and 6663 out-patients, as compared with 6768. The expenditure exceeded income by £584 13*s.*, this being partly accounted for by an increase in the hospital's supply of radium. A special radium fund has been instituted for which donations are requested.

April 8th.

BRISTOL AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

THE Bristol papers have published illustrations of the new buildings as they will appear when completed. The impression which these give is that the great tower will rather dwarf everything in its neighbourhood, but that it will at the same time be one of the finest pieces of modern architecture in the country. Certainly Bristol will be fortunate in adding so magnificent an adornment to her none too attractive streets. The controversy about the administration of the University drags its weary course along. Apparently Members of Parliament are accessible to those who are anxious to stir up trouble, for questions are being asked still in the House of Commons. The lecturer whose letters to the press are responsible for a prolongation of a controversy which would otherwise have died a natural *death has been relieved of his duties during the coming* summer term. He, however, claims the right of appearing before the council to defend himself.

Insurance Medical Service in Bristol.

The medical profession in Bristol has finally decided to continue the present panel service under the Insurance Act for the time being, instead of pressing for the changes contained in a scheme put forward by the Medical Federation, Limited.

Bristol Medical Dramatic Society.

A most successful week of performances has just come to a close. The society this year chose the *Manœuvres of Jane*, and though this was in some respects an ambitious flight, it was amply justified by the results. The cast was good throughout, though one or two familiar figures were missed, and the "houses" were most satisfactory. As usual, the performances were given at the All Saints' Hall.

The "Bristol Medico-Chirurgical Journal."

The March number of this quarterly journal is particularly interesting because it carries as frontispiece a portrait of Dr. R. Shingleton Smith, who retires from the editorship after 21 years of excellent service. His successor is Dr. P. Watson-Williams, who has had a long experience as assistant editor, a post now filled by Dr. J. A. Nixon, whose office as editorial secretary is in turn filled by Dr. J. M. Fortescue-Brickdale.

Bristol General Hospital.

The new wing, which is being built of reinforced concrete, is a source of considerable interest to Bristolians, who are not accustomed to this method The new laundry is already in use, and it is probable that the opportunity afforded by all these changes for an extension of the pathological department will be seized without delay.

The Health of Torquay: Decrease of Vaccination.

The medical officer of health of Torquay, Dr. T. Dunlop, in his annual report for 1912 states that the birth-rate was 14·5 per 1000, the death-rate being 12·2 per 1000. Dr. Dunlop says that the district was formerly an exceptionally well-vaccinated one, but now it had become poorly vaccinated. The conscientious certificate exemptions in 1907 were 30, but in 1911 they numbered 230. He adds that if a small-pox epidemic should occur it will cost a considerable sum of money, and cause the district to be avoided by all who can afford to do so.

Taunton Rural District.

The medical officer of health of the Taunton rural district, Dr. H. J. Alford, in his annual report for 1912 states that the death-rate was 11·7 per 1000. The birth-rate amounted to 15·4 per 1000. Infantile mortality was at the rate of 79·4 per 1000. During the year 43 notifications of infectious diseases were received, and of this number 14 were of pulmonary tuberculosis. Dr. Alford states that a tuberculosis dispensary has been opened at Taunton. In alluding to the danger of using milk from tuberculous cows, he says that the number of infected cows in the county of Somerset was very large, but no doubt much could be done by future legislation to counteract this evil.

Somerset Education Committee and the Dental Treatment of School Children.

At the last meeting of the Somerset education committee it was stated that it was practically impossible to get the school managers to grant a fixed sum for dental services for the school children, as out of 494 schools in Somerset only 94 had done so. It was decided that when the present temporary appointment of the dental surgeon had terminated he should be reappointed at a salary of £300 per annum, exclusive of travelling expenses.

Death of Dr. Herbert Stanley Jenkins.

News has been received of the death of Dr. Stanley Jenkins, a former Bristol student, who was distinguished not only by academic success, but also by personal charm. His death occurred at the early age of 38, at Sianfu, in Central China, where he was working as a medical missionary. Sianfu was a storm centre during the recent revolution, and though Dr. Jenkins escaped the perils that beset his colleagues owing to his absence on furlough, he was indirectly a victim of the same catastrophes; for the outbreak of typhus fever to which he apparently succumbed is no doubt traceable to the exhaustion of the city population by fire, sword, and famine. Another of his colleagues, Dr. Cecil F. Robertson, has been carried off by the same outbreak.

April 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The "National Health Week."

THE "National Health Week" is being celebrated in Dublin by a Health and Housing Exhibition held in the gardens of the Rotunda Hospital. The exhibition was opened last Monday by His Excellency the Lord Lieutenant, and on Tuesday a lecture on "Food" was delivered by Professor W. H. Thompson. The housing section shows a number of model cottages suitable for country districts, and also exhibits plans and maps suggestive of improvements in town planning. There is a section for the treatment of the tuberculous, which contains a model tuberculosis dispensary and also a milk depôt with pasteurising plant. Another feature is a dental clinic, such as is suggested for primary schools. The management of the exhibition is in the hands of the Women's National Health Association. In various provincial towns "Health Week" is being observed by courses of lectures on health subjects.

Royal College of Physicians of Ireland.

At a meeting of the President and Fellows of the Royal College of Physicians of Ireland held on April 4th the following were duly elected Fellows of the College:—Mr. Albert Croly, Rathfarnham; Dr. Robert J. Rowlette, Dublin; and Captain W. Porter MacArthur, R.A.M.C.

The Certification Scheme.

The one topic of interest in medical circles in Ireland during the past week has been the scheme for medical certificates put forward by the Irish Insurance Commissioners. A meeting of the medical profession of Dublin was held on March 28th at the Royal College of Surgeons, and after heated discussion was adjourned to April 2nd. After further debate a resolution was passed rejecting as totally inadequate the terms offered by the Commissioners for certification, declining to join the panel unless and until the minimum terms agreed to at the general meeting of the profession in Ireland are conceded, and calling on all medical practitioners in the district to adhere to this resolution. Only some 11 medical men had at the time of the meeting put their names on the panel for the City of Dublin, though there are about 500 practitioners living in Dublin or its immediate neighbourhood. The attitude of medical men throughout the country is the same as that of their colleagues in Dublin. Only in three county boroughs and in two or three counties have the panels filled. The scheme of the Commissioners is, therefore, an almost unqualified failure, though they took extraordinary measures to gain acceptance for it. Not content with claiming without authority the approval of the Conjoint Committee and of the Insurance Committees, the Commissioners extended the time for going on the panels by a week, and the Medical Commissioners, by means of an interview with a representative of one of the morning papers, took especial pains to clear away certain misunderstandings which had naturally arisen from the slovenly drafting of the contract which medical men were asked to sign. At a meeting of the Poor-law Medical Officers' Subcommittee of the Irish Medical Association held in Dublin on April 3rd, resolutions were unanimously passed condemning the action of the Commissioners, and promising the strongest opposition.

Belfast Medical Men and Medical Benefit.

A very largely attended meeting of the medical practitioners of Belfast was held in the Medical Institute, Belfast, on April 2nd, Sir John W. Byers being in the chair. Mr. T. A. Davidson, who acted as convener, gave an account of the conference between the Conjoint Committee and the Treasury Medical Committee (THE LANCET, April 5th, p. 992) in regard to rates of remuneration under the proposed extension of medical benefits to the six Irish county boroughs. After a very full discussion the following resolutions were passed:—

1. That this meeting of medical practitioners resident within the county borough of Belfast approve of medical benefits under the National Insurance Act (1911) being extended to Ireland on the following terms: a capitation fee equal to that paid for insured persons in Great Britain—i.e., 7s. for each insured person per annum, including the treatment of tuberculosis, but excluding medicine and surgical appliances.
2. That this meeting of the medical practitioners in the county borough of Belfast are strongly opposed to treat dependents under the National Insurance Act.

It was also decided that the delegates appointed to represent the Belfast medical practitioners at the conference to be held in London should not agree to any other terms. Mr. Davidson and Dr. G. Elliott were appointed the representatives of the Belfast medical profession to the conference to be held in London with the Treasury Committee and the Friendly Societies. It appears now that there are in Belfast 143,000 insured persons.

Ulster Hospital for Women and Children, Belfast.

At the annual meeting of the supporters of this hospital held on April 3rd it was reported that during the past year there were 196 children, 89 women (gynæcological), and 2 women (maternity) admitted into the wards; while in the outpatient department 2363 (including 343 in the ophthalmic department) children, 680 women (gynæcological), and 270 women (maternity) were treated. Financially there was a balance in favour of the hospital of £63 11s. 7d., which added to the balance from 1911 of £210 14s. 6d., gives a balance forward to 1913 of £274 6s. 1d.

Liability of Consumptives.

At co. Monaghan quarter sessions on April 5th hi honour Judge Johnston delivered judgment in a case o unusual interest which had been heard at the last sessio A boarding-house keeper of Rostrevor, a health resort in c Down, sued a merchant in Monaghan, executor of the of a man, for injuries committed by that individu (deceased) when residing as a lodger in her house in Jun 1912, the allegations being that he infected the house an furniture with a contagious disease—pulmonary tuberculo- His Honour gave a decree for the full amount of th plaintiff's loss through the disinfection of the room and th destruction of some of the articles, and a further sum of for the loss of lettings, making altogether £16 4s. 2d.

April 8th.

ROYAL METEOROLOGICAL SOCIETY.—The annu dinner of this society will be held on May 20th at t Trocadero Restaurant, Shaftesbury-avenue, Piccadilly Ci All communications should be made to Mr. W. Mari Assistant Secretary, at 70, Victoria-street, London, S.W.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Tobacco Angina.

M. Fiessinger discussed before the Academy of Medicine on April 1st the part played by tobacco in the serious effects of angina pectoris. Certain anginal neuralgias are induced by tobacco, but they are benign in character and disappear with the [illegible] fatal cases syphilis must be [illegible] related three cases in which [illegible] led to mercurial treatment, which was followed by immediate improvement, after all other remedial measures had failed. The diagnosis of serious tobacco angina—*angine scléro-tabagique*, as Huchard called it—cannot be admitted unless syphilis has been previously excluded.

Biology and the Kinematograph.

At the Société de Physique M. Guillaume recently discussed the application of the kinematograph by Dr. Comandon, not merely for recording the movements of large organs, such as the heart, but also for following the life process up to its ultimate manifestations. By its means, he reminded his hearers, the circulation and the intimate mechanism of respiration can be demonstrated; the life phases of bacteria can be followed step by step, their mode of locomotion fathomed, and their struggle with the organism witnessed. By a retarded movement of the kinematograph, taking only one picture every minute, and then causing the film to rotate at the ordinary speed, the development of a seed, the growth of a flower, the metamorphoses of a larva, can be followed. The prospect is captivating, and the retarded kinematograph is undoubtedly a most useful means of instruction. Finally, a particular experiment in animal physiology can be made once for all, and where this can be done by means of the kinematograph the experiment can be repeatedly demonstrated to students.

Surgical Intervention in Tuberculosis Peritonitis.

M. Kirmisson considers surgical intervention indicated in certain cases of tuberculous peritonitis, in support of which view he cited many examples before the Société de Chirurgie on April 2nd. While performing a laparotomy in a case of intestinal occlusion he found, besides an intestine perforated by tuberculous nodules, two bands of adhesion which kept the intestine kinked. He divided them and kept the patient, who was cured, under observation for a year. This happened also in another case. At other times it was not bands but an agglutinated mass which caused the occlusion, and in such a case operation is ineffective, as he had found by trial. M. Léjars said that he had occasion to operate in a certain number of cases. In one case that presented all the signs of [illegible] cured. M. Léjars then recalled that there are in some forms of peritonitis pseudo-occlusions often simulating appendicitis Merely opening the abdomen suffices to overcome such conditions, which are due only to acute localised peritonitis. Finally, M. Quénu added the testimony of cases from his own practice in support of surgical intervention.

Vaccination against Anthrax.

M. Roux has brought before the Académie des Sciences the results of the work of M. Declainche and M. Vallée, who for 12 years have been pursuing systematically the study of vaccination against anthrax, with the result that they have been able progressively to improve on the technique of their first operation. They have now made public a process that enables them to produce really attenuated strains of the bacillus anthracis, strains that it has hitherto been impossible to obtain. Vaccines prepared therefrom ensure, with a single vaccination and without any risk, the perfect immunisation of animals exposed to infection. As 345,000 cattle have been vaccinated by this method with complete success in the past three years, the authors consider the problem of vaccination against symptomatic anthrax definitively settled.

Impure Salt.

M. Andouard has been studying salt, which the bacteriologists consider a veritable hotbed of microbes of all kinds and a possible source of more or less severe infections. M. Andouard first showed that sea water near the shore, and consequently in the immediate vicinity of the salt-beds, contains considerable quantities of bacteria, of which the preliminary clarification beds favour the multiplication. This naturally is augmented by the raking of the beds with unclean instruments and the feet of the waders. The grey salt used for cooking and baking is of this kind. The fine salt is less rich in harmful germs, though not entirely exempt. In spite of the re-dissolving and clarification of the [illegible] Ermengem found the bacillus botulinus, a cause of very grave intoxications M. Andouard concludes from his observations that salt is a substance more or less impure from both the chemical and the bacteriological points of view, and that serious measures are called for refining, sterilisation, and clean packing—to put an end to the disorders that may be caused by this product.

April 7th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Calcutta Swamp.

THE state of the Calcutta streets during rain recalls the fact that the city was built upon a swamp, and is consequently condemned to suffer whenever a few inches of rain fall. In the monsoon the subsoil water is but a few inches from the surface, and the only means of remedying the effect of the excess of water from below and above would be an unusually extensive drainage scheme. The chief engineer has shown in the course of a lengthy note how the existing drainage of Calcutta has become too small for the work forced upon it by the growth of the city. The remedy is obvious, but the means of carrying it out by no means springs so readily to the eye.

Physique of Educated Indians.

An article appears in the February *Wednesday Review* from the pen of the Hon. Dr. T. N. Nair on the Physical Degeneration of the Educated Indian. Dr. Nair attributes this degeneration to early marriage, malnutrition, injurious environment, and overstudy, and advocates medical inspection and feeding by the State of all school children.

The Supply of Hospital Nurses in India.

The report of the Lady Minto Nursing Association, which shows that the association is continuing and gradually extending its sphere of usefulness, has just been issued. During the year the nursing sisters throughout India attended some 514 cases, 309 of which were medical, 68 being cases of enteric fever, 96 maternity cases, and 40 infectious cases. 138 applications for nurses had to be refused owing to no nurse being available. The highest number of cases attended in any previous year was 477 in 1910. During 1912 the number of non-subscribers' cases attended was 184, and the fees realised from these cases amounted to Rs. 17,166. The total subscriptions received during the year amounted to Rs. 38,730, and the total fees to Rs. 48,104, there being in all 1608 subscribers. During the year 10 nurses were sent out to India, all except 2 of them having received their training at London hospitals.

Dr. T. F. Pearse, late Medical Officer of Calcutta.

Dr. Pearse, having retired from his post as medical officer of health of Calcutta, is leaving here and will arrive home probably about the end of May. At a special meeting of the Calcutta Corporation, held at the Central Office on March 5th, a resolution was passed placing on record its high appreciation of the services which Dr. Pearse had rendered to the city and expressing its regret that reasons of health had rendered his resignation necessary. Dr. Pearse, who has been connected with the Calcutta Corporation for 15 years, has been its health officer for six years, and has done excellent work during his term of office.

King George V. Anti-Tuberculosis League, Bombay.

This League, which, under the presidency of Lord Sydenham, the Governor of Bombay, and a distinguished committee, was formed to commemorate the Coronation Durbar and the visit of their Imperial Majesties, the King Emperor and Queen Empress, to this country, has issued a plan of campaign and made an earnest appeal for contributions. The plan of campaign includes the notification of the disease, the establishment of tuberculosis dispensaries, the education of the people, the medical inspection of school children, the supervision of milk and food supplies, and the general relief of distress caused by the bread-winner of a family developing consumption. The scheme is therefore a very comprehensive one and if it can live up to its programme should materially benefit the province, especially as it is the intention of the league to emphasise the importance of the establishment of hospitals for advanced cases, of sanatoriums and farm colonies, of open-air schools and homes for cripples, and the segregation of infected purdah women in suitable institutions, these institutions being provided for and maintained by municipal bodies or outside philanthropic agencies with or without Government aid. Towards the general scheme Mr. Ratan Tate has promised to contribute Rs. 1,50,000, the Government of Bombay an annual donation of Rs. 19,000 for three years, and the municipal corporation of Bombay has sanctioned a similar amount for the same period, while several commercial firms have promised assistance. It has also been arranged that there should be an enrolled list of annual members and life members paying a subscription of Rs. 5 and Rs. 100 respectively. Dr. J. A. Turner and Dr. N. H. Choksy are the honorary secretaries.

King Edward VII. Memorial Sanatorium at Lotni, Bhawali, Naini Tal District.

Major A. W. Cochrane, I.M.S., the superintendent of the sanatorium which was raised as a memorial to the late King by the people of the United Provinces, has issued his report for 1912. Up to Dec. 31st 54 patients were admitted, comprising 45 males and 9 females, the percentage of those giving a history of tuberculous lung disease in near relatives being 55 per cent. Of 36 patients who left the sanatorium during the year the average stated length of illness before admission was 388 days. The average stay of the patients in the sanatorium was 81·44, the maximum being 183 and the minimum 17 days. The result of the treatment, not including 6 cases which stayed less than 1 month, was as follows: in the first and second stages (11 cases) no deaths, 1 not improved, 1 improved, 2 much improved, and 7 disease arrested. In stage three (19 cases) 1 died, 5 not improved, 4 improved, 5 much improved, and 4 disease arrested. This gives 63·63 per cent. of cases of arrested disease in stages 1 and 2 and 21·05 per cent. in stage 3.

The Viceregal Lodge Fund for the Turkish Army.

A sum of Rs. 21,842-7-3 was sent to Constantinople on behalf of Her Excellency Lady Hardinge's Fund for the relief of the women and children of Turkish killed and wounded. This sum has now reached its destination, and, with the permission of Her Excellency, has been added to Lady Lowther's Fund, which deals with the absolutely destitute women and children who have lost their all owing to the war. There are at present 15,000 refugees entirely dependent on Lady Lowther's Fund, of whom 6000 are the families of the Turkish soldiers—dead, wounded, or lost—and it is for the maintenance of these that Lady Hardinge's Fund has been utilised. The Turkish Government has in most cases been able to provide housing for them, but they are entirely dependent on charity, I understand, for all the other necessaries of life. They are now being supplied from the Fund with bread, charcoal, bedding, and garments, and in some cases with milk, rice, medicine, and beans.

The Ghent Exhibition.

Surgeon-General Sir A. M. Branfoot will represent the Government of India at the Ghent International Exhibition of Tropical Diseases, which has been fixed for the spring. Exhibits relating to malaria, kala-azar, cholera, and small-pox are being collected for inclusion in the British collection for the Exhibition.

Bangalore Improvements.

As a result of the inspection late last year by Major J. C. Robertson, I.M.S., of the sanitary requirements of the civil and military station of Bangalore, the Government of India have now sanctioned a special grant of four lakhs of rupees (£25,000 sterling) to be expended exclusively on sanitation. This will include further relief of congestion in the general bazaar by the demolition of insanitary dwellings, compensation for road opening, and new tenement extensions.

Plague at Jhelum.

Plague has broken out in the city of Jhelum. During the last few days about half a dozen men were taken ill, and all of them succumbed to the disease. At first the disease remained confined to the upper part of the city, but now it is spreading to the other parts. The first case took place in the sweepers' huts, but now it has extended further. Dead rats are being thrown into the streets by the people, a practice that should be stopped at once. In consequence of this outbreak the Jhelum cantonment is placed out of bounds.

The Dangers of Petrol.

An unfortunate accident illustrating the danger of using petrol for cleaning purposes occurred in Lahore recently. A lady had cleaned a pair of gloves with petrol early one morning, and after doing so hung the gloves up in the verandah. In the afternoon when going out she put on the gloves, and was just leaving her drawing-room when she noticed that the fire needed attention. She picked up the poker and stirred the fire, when her gloves suddenly burst into flames. She had the presence of mind to thrust her hands under a heavy rug which was handy, but both hands being burnt she was unable to press the rug down on them. It was some time before the flames were extinguished, and the lady's arms were severely burned. It is worth while to call attention to this case because there is a very general impression that the small amount of petrol used for glove-cleaning, &c., evaporates rapidly, and that a very brief time is sufficient to prevent all possibility of danger. In this case the gloves had been hanging for several hours in the open air before they were used, but enough petrol remained in them to cause a serious accident.

The Madras Water-supply.

The Government of India has submitted for sanction to the Secretary of State a project for a reservoir connected with the Madras water-supply which is estimated to cost 20½ lakhs of rupees.

Karachi's Water-supply.

In a recent report the chief engineer of the Karachi municipality shows that for an expenditure of about 6 lakhs of rupees he can provide for all the reasonable requirements of Karachi for the next ten years. For the more distant future there is a project for damming the river Malir about 29 miles away, which will guarantee a practically unlimited and inexhaustive supply. It remains for the municipality to deal with the financial aspects of the situation.

March 14th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Health of the Australian Navy.

THE report for last year states the strength of the navy at 14 vessels, carrying 3450 men. The number of cases of disease and injury entered on the sick list was 2691, which was an increase of nearly 50 per cent. on the average for the previous five years. The invalidings numbered 56. There were 13 deaths. The average number of daily sick was 80·7. The increase in the sick list was due to minor ailments, and the venereal statistics were said to be satisfactory.

Maternity Bonus.

The Commonwealth maternity bonus has now become very generally claimed, and it is estimated that the first year's payments will total over £600,000. The first prosecution for making a false return was heard in Victoria, and the accused woman was fined £10 and ordered to return the amount of the bonus. The mother had obtained it by forging the nurse's signature.

New South Wales Public Health Department.

Dr. J. Ashburton Thompson has retired from the position of principal Government medical officer and President of the Board of Health. Dr. Thompson has done good work during his occupancy, and is recognised as a leading authority on leprosy and bubonic plague. It was owing to his work in Sydney that bubonic plague became definitely recognised as a disease of rats, and probably conveyed to man by means of fleas. His retirement will be made the occasion of a rearrangement of the work of the department. The position of Government medical officer will be taken by Dr. O. Paton. At present there are three separate departments of microbiology, public health, and hospitals and charities. It is proposed to amalgamate these under one head. The medical inspection of schools will be made a separate department Dr. F. Tidswell has resigned his position as director of the Bureau of Microbiology.

Australian Association for the Advancement of Science.

The section of sanitary science and hygiene at the recent Congress of the Australian Association for the Advancement of Science recommended —

That a sanitary committee be formed to report on the sanitary control of small towns and rural districts, that medical officers of health should have special [illegible]
be whole time officers,
should be appointed, t
and sanitary science be
Governments of Austra
ference of chief medic
measures for control of tuberculosis in cattle and pigs

Insane Immigrants.

The Inspector-General of Insane for Victoria (Mr J. Jones) has drawn attention to the number of immigrants received into the lunatic asylums, a feature which has been noted also in America Mr Jones has been asked by the Government to furnish exact information on the subject.

Medical Inspection of School Children

The report of the Victorian school medical inspectors states, *inter alia*:—

r school children
in this particular
beginning in the
alnutrition occurs
from 3 per cent
5 per cent —i e,
o attempt has yet
children A large

endemic

Vital Statistics of Victoria

The report for 1912 of the Government statistician states —

The number of marriages—11 738—exceeded by 650 the total for the preceding year and the resulting marriage rate—8 66 per 1000 of population—was the highest experienced in the State for 52 years The births numbered 35,817, of which 16 879 occurred in Greater [illegible]

death rate was the highest for nine years The deaths of children under one year of age numbered 2669 for the whole State and 1523 for the metropolis, as compared with 2270 and 1139 respectively in 1911 There was a fairly large reduction in the death rate from tubercular [illegible]

A Large Family

A woman at Katoomba, New South Wales, recently registered the birth of her twenty-fifth child She walked a distance of three miles to the registrar's office, carrying the child, on the fifth day after its birth.

Personal.

Professor H. B. Allen has returned to Melbourne after an extended holiday in Great Britain and Europe, and resumed his duties at the University.—Dr. G. Rothwell W. Adams has resigned his position as surgeon to the Women's Hospital, Melbourne, after holding it for a period of 25 years Dr. Adams is lecturer on obstetrics and gynæcology in the University of Melbourne —Dr. G. C. McK. Mathison, a Melbourne graduate, who has for some years been engaged in research work at the Lister Institute, will return to take up a position at the Melbourne Hospital in August next.

March 8th.

Obituary.

SAMSON GEMMELL, M D, C.M. GLASG., F R F P & S GLASG,

PROFESSOR OF THE PRACTICE OF MEDICINE IN THE UNIVERSITY OF GLASGOW, PHYSICIAN TO THE WESTERN INFIRMARY AND CHILDREN'S HOSPITAL, GLASGOW

THE medical profession and the general public of Glasgow and the West of Scotland have suffered a great loss in the death of Professor Samson Gemmell, of the chair of Practice of Medicine in the University of Glasgow. Dr Gemmell was apparently in good health up to a few hours before the sad occurrence, which took place at his residence, 17, Woodside place, on April 4th At the beginning of the week he presided at the meeting of examiners for the final examination in medicine at the University. On the day of his death he paid his customary visit to the Western Infirmary, and there were no indications of approaching illness at that time. Three hours after leaving the infirmary he became unwell, and expired in his own house before medical assistance could be rendered. Death was due to heart failure

Dr Gemmell was born in 1848 in Catrine, Ayrshire. He studied medicine in the University of Glasgow, where he graduated M B, C M with honours in 1872 and M.D. in 1880. In 1880 he also became a Fellow of the Faculty of Physicians and Surgeons of Glasgow After completing his medical curriculum he became a resident physician in the Royal Infirmary, and also acted for a short period as demonstrator of anatomy He then became medical superintendent of the City of Glasgow Fever Hospital, after which he started in consulting practice. He was appointed assistant to the professor of medicine in the University, a post which he held till 1880, when he was appointed to the chair of practice of medicine in Anderson's College Medical School In the year 1900 Professor McCall Anderson was transferred from the chair of clinical medicine to that of practice of medicine in the University, and Dr Gemmell was appointed by the University Court to the chair of clinical medicine He held that chair till 1908, when on the death of Sir Thomas McCall Anderson he was appointed by the Crown to the chair of practice of medicine, which he has since held Dr Gemmell in the early stages of his career was a dispensary physician in the Western Infirmary In 1886 he was appointed physician to the Royal Hospital for Sick Children, and in 1887 physician to the Royal Infirmary From the latter post he was transferred in 1894 to the Western Infirmary During his life he built up in Glasgow a great reputation as a teacher and a medical consultant He was admired and respected by all for his medical knowledge, his sound judgment, and his intellectual honesty, and his kindness of heart and friendly interest endeared him to all who came in contact with him.

Dr Gemmell was a sparing writer, and contributed little to medical literature Early in his teaching career he wrote an excellent chapter on Physical Diagnosis of Diseases of the Chest and Abdomen for the second edition of Finlayson's Clinical Manual; but this was almost his only published work

Dr William R Jack sends the following appreciation:

"By the death of Professor Samson Gemmell the University and the medical profession of Glasgow have lost one of their most striking personalities He was the last of an epoch; a man in whom were all the virtues of the older school of medicine, based upon wide clinical experience and a quick insight into the nature of disease He was not neglectful of detail, but he had the happy faculty of selecting from among the details of a case the points which were most essential to its comprehension, and of so emphasising these in his demonstration of it that the malady formed a picture not soon to be obliterated from the recollection of his hearers. In his systematic lectures his method was the same, but it was at the sick bed, where his students were closely gathered round him, that it was seen to its fullest advantage, and that his graphic and incisive eloquence most firmly riveted their attention. They played no mere passive part in his demonstrations. His penetrating questions and his caustic comments, if they caused dismay among the laggards, yet spurred the better men to the best that was in them. His hold upon his auditors was strengthened by the fact that he had no more mercy for his own errors than for theirs. Where his diagnosis had been at fault he never sought to hide or palliate the mistake; rather he insisted upon its lessons both for himself and for his students. His personality was masterful, and though his criticism might at times be harsh, those who knew him knew that it was equal, and that he had not two measures. Such honesty, coupled with such diagnostic skill, soon commanded confidence, and at the time of his death he had the largest consulting practice in the West of Scotland. It contributed to this result that he was intensely human, that a patient was to him no mere diagnostic problem but a piece of suffering humanity whose weakness might lean upon his strength. In his wards, as in private, his patients drew vitality from him, and to young and old he was alike a friend. The characteristics thus briefly indicated distinguished him in private as in his professional career. He was a man of wide reading and broad culture, to whom, though when he pleased there could be no more charming companion, a book was as much a friend as a person. He had strong opinions, and he was fearless of criticism. He was outspoken in advocacy, as in condemnation; if he made enemies he had also firm friends, loyal to him as he was loyal to them. He hated anything mean, and cant was the chief object of his hatred. The generations of students who came under his influence learned from him not medicine only, but straightforwardness, courage, and fidelity to truth."

JORDAN LLOYD, M.S. DURH., M.D., M.SC. BIRM., F.R.C.S. ENG.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF BIRMINGHAM; SENIOR SURGEON TO QUEEN'S HOSPITAL, BIRMINGHAM.

WE regret to record the death on April 4th of Professor Jordan Lloyd, the eminent Birmingham surgeon. He died—as he would have wished to die—in harness, for his fatal attack of angina pectoris came on after a morning's operation at Queen's Hospital. His loss will be widely felt in Birmingham and throughout the Midlands.

Jordan Lloyd was born in Birmingham in 1853. He was educated professionally at the old medical school of Queen's College, Birmingham, and at the University of Durham. After qualifying at the Society of Apothecaries in 1877 he obtained the Membership of the Royal College of Surgeons of England in the following year, and the Fellowship two years later, when he also took the M.B. and M.S. degrees of the University of Durham. Shortly after the foundation in 1900 of the University of Birmingham Mr. Jordan Lloyd received the degrees of M.B., B.Ch., and M.Sc. from that body, and in 1904 the M.D. degree of Birmingham was conferred upon him.

His long connexion with the visiting staff of Queen's Hospital began at the end of 1880, when he was appointed casualty surgeon. Two years later he was promoted to be surgeon, and this post he held with distinction for the remaining 30 years of his life. During this time he steadily built up a high reputation as an operative surgeon and as a teacher, and his appointment as co-professor of surgery in the university of his native city was a well-deserved honour. From 1883 onwards Mr. Jordan Lloyd wrote frequently on surgical subjects, and between 1887 and 1897—the years of his greatest literary activity—numerous papers from his pen were published in THE LANCET. Besides his appointment at Queen's Hospital Mr. Jordan Lloyd was consulting surgeon to a number of local institutions. He was a justice of the peace for the city of Birmingham, a lieutenant-colonel in the Royal Army Medical Corps, Territorial Force, and officer commanding the 1st Southern General Hospital, South Midland Division.

Professor Robert Saundby sends the following appreciation: "I have known Mr. Jordan Lloyd since he came to the General Hospital as resident surgical assistant in 1876. I was much impressed by the ability he displayed, and I had some conversation with him about his education, urging him to try for higher qualifications, as he had not entered for the first Fellowship or the London M.B. He told me his father thought it was unnecessary, and as it was his intention to join his father's practice he should only try for the ordinary diplomas. However, his own and probably his father's views became modified by his wonderful success as a student, and he was undoubtedly encouraged greatly by his teachers, the late Mr. Sampson Gamgee, by Mr. J. Furneaux Jordan, to both of whom he always expressed himself as owing much, and by Mr. Lawson Tait, who early appreciated his surgical talent. I watched his progress with sympathy, and although others better qualified can express what was thought of his originality and skill as a surgeon, I saw enough to show me that he stood in the front rank as an operator, bold in resource and marvellously capable of carrying out his carefully devised plans. His almost boyish enthusiasm for his work lasted throughout, and enabled him to overcome the disadvantages of a frame never robust and of the ill-health that weighed him down during recent years. He was a charming speaker, with something to say that was always fresh, and no man enjoyed greater popularity as a teacher and consultant; in both these capacities he will be greatly missed. He was of a singularly affectionate disposition and possessed a winning manner which gained him many friends and softened his relations with those who at times differed from him in policy. His domestic life was especially happy. His last words were highly characteristic of the man: 'What shall I do? I shall have to give up my work.' He lived for his work; he could not take holidays; when he went away he fidgeted all the time and wished himself back at work. Although he had been warned of the dangerous nature of his recent attacks he would not reduce his work. He did four or five operations on the Friday morning, and unfortunately one of the patients, a child, stopped breathing. He performed artificial respiration himself, and had the satisfaction of seeing it recover, but it is only too probable that he gave his own life in exchange. He drove home in a cab, but on arrival he collapsed. He lay down on the hearth-rug in front of the dining-room fire and had a terrible anginal attack which was relieved by amyl nitrite. He sat on the sofa, but after a short interval he complained of a return of the pain, drew two or three deep breaths, and died before medical assistance had arrived."

Professor Gilbert Barling writes:—"Mr. Jordan Lloyd was a very brilliant surgeon, especially as a manipulator—bold, quick, and very ready in any difficulties. He had above all things a most keen and vivid interest in his work. It was not merely a matter of earning an income or holding an office. The study of disease in itself and the opportunity to relieve it was to him a real gratification and an ever-present interest. He was a very fine teacher and lecturer, and the address in Surgery which he gave at the meeting of the British Medical Association in Birmingham in 1911 was a brilliant performance. In his earlier days, when, of course, he had more leisure, he made a number of interesting inquiries and researches into various forms of surgical disease, and the papers he wrote at that time are still quoted as authoritative on the conditions of which they treated. It has been a matter of great regret to his friends and colleagues during the last few years that his health has seemed to be rather strained, and that he was not always able to do himself full justice. He will be long and affectionately remembered as a brilliant son of the Birmingham School of Medicine."

ALFRED CHUNE FLETCHER, M.R.C.S. ENG.

THE death has been announced of Alfred Chune Fletcher, surgeon to the Charterhouse, which occurred on March 30th. A large circle of friends and patients have learned the fact with great concern.

Alfred Chune Fletcher started life as a journalist, and his language, written or spoken, was always so selected, lucid, and to the point, that his literary training might have been guessed. He did his student's work at St. Bartholomew's Hospital in the late "seventies," and was house surgeon to Sir William Savory in 1881–2. He was well equipped in all branches of his profession, his thoroughness and close attention to details being combined with a keen therapeutic instinct. His practice was large outside his constant duties at the Charterhouse and the Merchant Taylors' School, where his straightforward and sympathetic manner won for him complete confidence, and he was concerned with many important patients. He was able to convey the true impression of his one object—which was *to do all that was possible for the best interest of the* patient. He thus represented in the eyes of those who knew him a typical picture of a sagacious practitioner.

"I shall be glad," writes a correspondent, who desires to remain anonymous, "if you will allow me to place on record a recognition of Mr. Fletcher's admirable qualities as resident medical officer at the Charterhouse, a position in which he was not only medical adviser to some 60 or so old men, often troubled with ill health, but also their official superior, and at the same time head of a medical service which embraces a fair number of nurses. Over all these people he might have ruled with sternness, but he appears invariably to have been gentle and most considerate, rendering many an act of kindness, and careful to spare with a gentleman-like instinct that does him honour the self-respect of the poor men subjected to his rule. The result, so I find, is, both among pensioners and among nurses, a high regard for his memory, genuine sympathy with his family, and gratitude that should stand for something when the great account comes to be cast up:—

Qui bene fecerunt, illi sua facta sequuntur."

Mr. Fletcher leaves behind him a wife, who has long been an invalid, and three daughters, two of whom are married.

GEORGE TEMPLETON, M.B., C.M. EDIN., F.R.C.S. ENG.

THE tragic death last week of Mr. George Templeton at the early age of 41 while ski-ing in Norway removes a prominent man from the list of the younger surgeons practising in London.

He was a native of Kilmarnock, and when quite a boy *proceeded to Edinburgh University and attended all the* necessary classes for qualification a year before the legal age for taking the University degree. In 1892 he graduated M.B., C.M. Edin. (with honours), and the same year took the English qualifications of M.R.C.S. and L.R.C.P., taking in 1896 also the surgical Fellowship. For some time he held the appointment of surgeon to the North-West London Hospital. As surgeon to St. Barnabas Home, Lloyd-square, *he did excellent work, and his charitable labours* there will be long remembered with grateful affection. He kept abreast of all the advances in modern surgery, and devoted considerable time to the study of general science and literature. He was a very proficient linguist, speaking German, French, and Italian fluently, and knowing something of other European languages, while he was passionately fond of music and played various instruments.

Mr. Templeton had a strong physique and was very fond of all outdoor exercises. Not long since he walked round the island of Arran, a distance of 60 miles, in one day. His death has come as a severe loss to many friends and patients.

HERBERT McDONALD PHILLPOTTS, L.R.C.P. LOND., M.R.C.S. ENG.

Mr. Herbert Phillpotts, who died at Nice on March 20th in his forty-eighth year, was educated at Plymouth and King's College School, London, and St. Mary's Hospital, and qualified L.R.C P. and M.R C.S. in 1890. He was a keen sportsman and had travelled considerably, though he was as devoted to Dartmoor as is his brother, Mr. Eden Phillpotts, the well-known author. [illegible]

there at his early death.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Paul Ascherson, extraordinary professor of botany in the University of Berlin, aged 78. In early life he had been a *general practitioner,* but lately had devoted himself entirely to botanical studies.—Dr. E. Schiff, *docent* of dermatology in the University of Vienna.—Dr. Alfred Genzmer, extraordinary professor of surgery in the University of Halle.—Dr. Arnold Heller, professor of pathological anatomy in the University of Kiel.

THE NATIONAL INSURANCE ACT.

THE INSURANCE ACT AND THE SUPPLY OF DRUGS.

MEDICAL benefit under the Insurance Act has now been in operation for a sufficient time to make it possible to form an idea of the effect of the Act upon the business of pharmacy. Especially in industrial centres, where such a large proportion of the population belongs to the insured class, the administration of medical benefit has brought about a great change in the character of the chemist's business, and there are indications that in course of time much of the exotic paraphernalia of pharmacy will disappear and the chemist's shop will become less of a general store and more of a place where pharmacy is practised. Already there has been a noticeable decrease in the sale of proprietary medicines and in "counter prescribing," and as time goes on the decrease will no doubt become more pronounced. Three months' experience has demonstrated that the extra work which has been thrown *upon the chemist is hardly compensated by the remuneration.* Except from Scotland, however, there have been few complaints concerning the rate of payment for drugs and dispensing, and it may be assumed that pharmacists are, on the whole, disposed to put on the credit side of the account the improvement in the character of their work, which has been one of the results of the operation of the Act. In Scotland the matter is not regarded in the same *light, for while a fair proportion of the work of the Scottish* pharmacist has always consisted of the compounding of prescriptions, this was hardly the case in England prior to the coming into operation of medical benefit. This difference is, in fact, emphasised by a representative body of Scottish pharmacists in a statement, which prefaces a demand for higher rates of payment for insurance work, wherein it is set forth that "while the English chemist has by means of the Insurance Act gained a considerable *addition to his* regular business, the Scottish chemist has seen a large number of his private clients brought under the Act, and as they now have their medicine supplied at the contract prices, he may fairly be considered to be a loser to the extent of the difference." From England and Wales, however, there appears to have been no expression of widespread discontent, but slightly improved terms have been embodied in the tariff of charges which form the basis of the new contract between pharmacists and Local Insurance Committees, beginning on April 15th. The principle upon which the tariff is based is the same as in Germany, a charge being made for each ingredient, according to its quantity and value, and a very modest additional fee for the time and skill required for dispensing. There are but few changes in the prices of the new tariff, and even in the aggregate they would amount to an almost negligible sum. For copying prescriptions the proposed remuneration is 1*d.* each, which can hardly be regarded as extravagant in view of the clerical work entailed. As to how far it will be found necessary to encroach upon the Drug Suspense Fund there are at present no means of making a fair estimate, but in Scotland, from calculations which have been made, it is considered that in many districts the drug bill will not swallow up the whole of the ordinary drug fund, in which case there would be no encroachment upon the floating 6*d.*

MIDDLESEX INSURANCE COMMITTEE.

The Middlesex Insurance Committee on April 7th had under consideration a letter from Mr. F. W. James, stating *that at a meeting of the Non-Panel Doctors' Association,* to which every qualified practitioner in Ealing whose name did not appear on the Middlesex panel was invited, it was decided to decline an offer of the Insurance Committee to allow medical men in Ealing to place their names on the panel for a limited class or number of insured persons. The association offered instead to establish a public medical service on the lines of the Ealing scheme, with no wage-limit other than that in the Act. Payment would be made out of a pool, not by capitation, but on a scale of fees for services rendered. The General Purposes Subcommittee recommended that the proposed service be not approved, and that full power be delegated to the subcommittee to deal—after consultation with the [illegible] Commissioners—

with any situation that might arise in the Ealing district after April 15th.

Mr. W. S. GLYN-JONES, M.P. (the Chairman), suggested that this proposal should be modified by the addition of the words :—

Provided that if the subcommittee recommend the appointment of a full-time officer or officers, a special meeting of the Insurance Committee will be summoned to confirm such resolution.

On a division, however, it was decided to omit the suggested additional clause on the ground that it would weaken the position of the committee in dealing with the situation in Ealing.

It was stated that the number of doctors on the panel in Middlesex was 520, and that 445 had signed renewal agreements. There were 347 chemists, and 305 had signed renewal agreements. Of 313,809 insured persons, 218,151 had selected their doctors.

LONDON INSURANCE COMMITTEE.

Some debate occurred at the meeting of the London Insurance Committee on April 3rd upon the following motion :—

That it be referred to the Medical Benefit Subcommittee to consider and report whether the present system of medical benefit provided under the Insurance Act, to insured persons in London, can be improved, and if so, to submit recommendations to give effect to their suggestions.

Mr. F. HARRIS, who moved the resolution, remarked that whereas prior to January last there were 1500 medical men engaged in contract practice, there were now 1258 medical men attending insured persons, who probably outnumbered by four to one those previously treated on a contract basis. He saw no reason to believe that the number of doctors on the panel would be greatly increased at the end of the first quarter. As there must be about 3000 medical men in London available for the treatment of insured persons, he urged that the question should be considered whether a conference with the medical profession would be useful in furthering the objects the Committee had in view.

Mr. E. B. TURNER, who seconded, said that the conditions of service under the Act must be modified if the number of medical men necessary for the proper working of medical benefit were to be obtained. It was the opinion of doctors all over the country that insured persons were not getting as good service as they were before the introduction of the Act. If better men could be attracted to the panels a double advantage would be secured in that the number of persons allocated to the individual doctor would be reduced, and patients would be attracted from any gentlemen who had gone on the panels after having failed to prove their ability in private practice.

Dr. H. H. MILLS thought Mr. Turner took an unduly pessimistic view. His information was the conditions of medical treatment among persons of the insured class were better than they had been before the Act came into force. He remarked that in three months only three or four serious complaints had come before the Committee. The working of the Act had made clear the inadequacy of medical provision in the whole of the east end of London and in all industrial districts.

Mr. EVAN JONES thought an efficient service under the Act was possible if the Committee approached the matter in the right spirit. He was not satisfied with the panel system.

The resolution was carried by a large majority.

The Committee instructed the Medical Benefit Subcommittee to prepare and circulate to members of the Committee only a return showing in the case of doctors on the panel with more than 1000 patients, the name and address of such doctor, the number of such patients so far as could be ascertained from the records of the Committee, and the amount of the cheques already paid on account of medical fees.

In view of the confidential character of reports dealing with complaints, the Committee approved the principle that the names of medical practitioners, chemists, and insured persons referred to therein should not appear on the agenda paper or other public documents of the Committee.

ORGANISATION OF THE MEDICAL PROFESSION.

We are asked to announce that at a meeting of members of medical unions and other bodies in east and north-east London and the county of Essex, held in the City on April 2nd, to "consider the best means of coördinating the work and policy of the said unions," a resolution to the following effect was carried with only one dissentient :—

That in view of the coming Representative meeting, the British Medical Association be requested to summon a meeting of the chairmen and secretaries of all Statutory and Provisional Local Medical Committees, and all other bodies interested in medical organisation, as soon as possible, for the purpose of considering the national organisation and consolidation of the entire medical profession.

NATIONAL MEDICAL GUILD.

The National Medical Guild has been established to acquire for the medical profession the immunities and powers of a trade union, as well as to provide various sorts of insurance for medical men; to obtain representation in Parliament; and for such other objects as may seem necessary or advisable. It is proposed to have members and branches in all parts of the United Kingdom. The rules of the Guild have already been circulated in London, and will be sent on application to any member of the profession elsewhere. The full scheme of insurance benefits is not yet ready for issue, but members joining now will have the full benefits of medical defence, either individually or collectively, as from the date of joining. The annual subscription is 1 guinea, which should be sent to the General Secretary, National Medical Guild, 34, Villiers-street, Strand, W.C. We are informed that the rules do not differ in any material respect from those of other trade unions.

THE MORTALITY OF THE PHTHISICAL UNDER SANATORIUM AND TUBERCULIN TREATMENT.

In a lecture at the Galton Laboratory, University College, London, recently, Mr. W. Palin Elderton, Fellow of the Institute of Actuaries, made some suggestive remarks on this subject. After alluding to the difficulties of making statistical comparisons of the results of treatment, it was shown that at present the most satisfactory comparison was reached by studying the subsequent mortality of those who had undergone various kinds of treatment. The results obtained proved that the mortality of incipient cases under sanatorium treatment was, generally speaking, over 3 times that of the general population, while advanced cases showed a mortality of 10 times, and far advanced cases a mortality of about 40 times, that of the general population. Some interesting results from Dr. Lawrason Brown's statistics of the Adirondack Sanitarium, New York, were discussed, but owing to the selection of patients and the increased proportion of early cases among the patients more recently admitted it was impossible to decide definitely to what extent sanatorium treatment had improved. The statistics showed, however, that at this particular sanatorium the authorities are now better able to say which cases will improve under treatment and which cases are cured. Using the same data, Mr. Elderton showed that the mortality of cases having tubercle bacilli in the sputum was $2\frac{1}{3}$ times to 4 times as heavy as that of the cases which were without this symptom, and this result sometimes enables us to estimate the extent to which data are influenced by the admission of an undue proportion of early cases. Examples of this were given in the course of the lecture. There was no evidence, Mr. Elderton considered, to prove that tuberculin as compared with ordinary sanatorium treatment appreciably lengthened the life of the consumptive. If the use of tuberculin had the very marked results claimed by some of its supporters, more definite evidence of its effect on mortality would have been anticipated.

In view of the National Health Insurance Act and its consequences, it is important that the mortality of consumptive patients after treatment should be studied fully with the view of ascertaining the relative value of the available methods of treatment, and the lecturer suggested that the only really satisfactory method of doing so was to try the treatments on similar cases—selected not by the stage of disease but at random—and to tabulate full particulars in order to see which gave the best results.

LONDON MEDICAL COMMITTEE.

A stormy meeting was held in Caxton Hall, Westminster, on April 8th, Sir Shirley F. Murphy presiding, the occasion being a conference called by the Local Medical Committee for the County of London. A resolution was adopted that a new committee should be chosen by local election in each borough, the existing committee, according to the proposer, being under a pledge to retire at the end of the quarter. This resolution, introduced as an amendment, took the place of one requesting the committee to continue to act for the present.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination held on April 1st, 2nd, 3rd, and 4th the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Norman John Ainsworth, Royal Dental Hospital; Robert Aspinall Stivala, Guy's Hospital; Frank Blake, City of London School, Antonio Mario Clément, St. Thomas's [illegible]

C[illegible]

Morris-Jones, St Mungo's College, Glasgow; Percival Randall, Cardiff University; Felix Tagger, Royal Dental Hospital; Charles Wilson Tomkinson, London Hospital; Cecil Vincent-Brown, Guy's Hospital; and Graham Arthur Osborne White, University College, Cardiff.

Physics.—Henry Hutton Castle, St. Thomas's Hospital; Bernard Crossley-Meates, Birkbeck College; Abdel Aziz Hassan El Zeneiny, Cairo and London Hospital; and John Reginald Houghton, Manchester University.

B[illegible]

At the Second Professional Examination in Anatomy and Physiology, held on March 27th, 28th, and 31st, and April 1st, 74 candidates presented themselves, of whom 43 passed and 31 were rejected. The following are the names of the successful candidates:—

Alexander William Charles Bennett, St Thomas's Hospital; Henry Cecil Herbert Bull, B.A. Cantab., Cambridge University and London Hospital, Ernest James Coombe, St. George's Hospital and King's College; George Lambert Cutts, Guy's Hospital; Arthur Thomas Dally, William Hood Dye, L.D.S. Eng., and [illegible] Hospital, Cyril Gould, University
[illegible] Greenish, B.A. Cantab.,
[illegible] Hospital; Frank Edmund
[illegible] niversity and St. Thomas's
[illegible] Husbands, Bristol Uni-
[illegible] dgson-Jones, Manchester
[illegible]
University; Harold Leslie Hughes, St. Mary's Hospital and King's College; Frank Bernard Jago, Manchester University; Nilkanth Shrivam Jatar, L.M. & S. Bombay, Bombay University and University College; James Kyle, Guy's Hospital;
Roy D[illegible] sity College; Cyril George
Learoy[illegible] Ernest Alfred Levieseur,
Guy's [illegible] Lindeman, St. Bartholo-
mew's [illegible] Little, Bristol University;
Eldon Munro Litchfield, New Zealand University and Guy's Hospital; George Samuel Bousfield Long, Guy's Hospital; Lewis Alexander McAfee, B.A. Cantab., Cambridge University and London Hospital; John Edward Carbery Maguire, and Rodney Honor [illegible]
Noel Spencer Nairne, St [illegible]
Navalkar, Bombay Un[illegible]
Frederick Munton Payn[illegible]
Smith, St. Thomas's Ho[illegible]
[illegible]
[illegible] Skelton, London
[illegible] ersity; Ambrose
[illegible] Whitehead, B.A.
[illegible] ge University and
[illegible] win Wilson, St.
Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery the following candidates were approved in the undermentioned subjects:—

[illegible] ge; *Geoffrey*
[illegible]
[illegible] ngton Eady,
[illegible] le Farnham,
[illegible]
University.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following is the list of the successful candidates at the examination held at the close of the forty-first session of the school:—

*Captain C. A. Gill, I.M.S., M.R.C.S., L.R.C.P., D.P.H.; *Captain F. P. Connor, [illegible]
Lond.; M. C. F[illegible]
J. R. Boyd, Co[illegible]
Layman, Coloni[illegible]
M.R.C.S., L.R.C.[illegible]
Camb.; F. C. D[illegible]
J. McDonald, [illegible]
Service, M.B., [illegible]
Service, M.R.C.S[illegible]
F.R.C.S.E.; Mi[illegible]
Beckett, Colonia[illegible]
L. S. McLean, [illegible]
Foreign Office, [illegible]
Service, M.R.C.S[illegible]
M.B., Ch.B. Edin.

* Passed with distinction.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., botany; Z., zoology; P., physics; C., chemistry):—

William Adams (Z., C.), Thomas Andrew Jamieson [illegible] (B.),
Robert Aitken (Z., C.), Marshall Thomson [illegible]
David Arthur (Z.), John Ashforth (Z., C.), [illegible]
(Z., C.), Henry Ernest Cyril Bacon (Z.), [illegible]

Baillie (Z., C.), Edward Thomas Boyle (B., P.), Archibald Campbell Brown (P.), Donald Eadie Brown (Z., C.), George Brown (Z., C.), Duncan Smith Buchanan (C.), Robert Stevenson Caldwell (Z., C.), Duncan Cameron (B., C.), Robert Barton Cameron (Z., C.), William James Simon Cameron (Z., C.), David Campbell, M.A., B.Sc. (P.), Malcolm Chalmers (Z.), Thomas Cuthbertson Christie (Z., C.), Alexander Ebenezer Cochrane (B., P.), Cyril Lockhart Cottle (Z., C.), Harold Livingstone Coulthard (Z., C.), John Salisbury Craig (Z., C.), Harold Arthur Cruickshank (Z., C.), Andrew Dick (Z., C.), James Hamilton Dobbin (Z.), Robert Kinnier Duguid (Z., C.), James Ferguson Duthie (Z.), Robert Taylor Duthie (B., Z., P.), Kenneth Henry Dyke (C)., Ralph Erskine (Z., C.), Fritz Eberhard Ferguson (B., Z.), *James Brown Fisher (C.), James Paton Fleming* (Z., C.), Walter Watson Forsyth (Z.), Robert Scoular France (Z., C.), Robert John Leslie Fraser (Z [illegible]
Galbraith (Z., C.), [illegible]
Alexander Gillander [illegible]
Osm [illegible] (B.,
P.), [illegible] don
(P.), [illegible] rles
Hendrie (Z.), George Mundell Hetherington (Z., C.), John [illegible]slop (Z., C.), James Robert Riddell Holms (Z., C.), Edward Porteous Irving (Z., C.), John Alexander Jenkins (Z., C.), Jacob Joels (Z., C.), William Hogarth Kerr, M.A. (B., Z., C.), William Mackintosh Kerr (B., P.), Peter Stewart Kinloch (Z., C.), Patrick Joseph Aloysius Lavelle (Z., C.), James Liddell (P., C.), Albert Ernest Lillicrap (Z., C.), William Wilson Lundie (Z., C.), Kenneth M'Alpine (Z., C.), Hugh Ernest M'Coll (P., C.), William Ritchie M'Crae (Z., P.), John Ronald M'Crindle (Z., C.), Arthur Daniel Clark M'Gowan (B., C.), Alexander M'Cheyne Macintosh (Z., C.), John Ebenezer MacIntyre (Z., C.), Donald James M'Kinnon (Z., C.), John Macleod (Z., P., C.), Findlay Kerr Macmillan (Z.), Donald Macqueen (Z., C.), William M'William (Z.), John Marshall (Z., C.), George Macleod Millar (Z., P.), Archibald Stewart Miller (Z., C.), William Duff Miller (Z., C.), David Stephen Mitchell (Z., C.), Livingstone Mitchell (B., Z., P.), James Moffat (Z., C.), John William Morton (Z.), James Robertson Jack Mylles (Z., C.), Douglas John Nicol (Z., C.), William Nicolson (Z., C.), John Bernard O'Neill (B., P. C.), William Harold Palmer (B., Z., P.), James Walker Patterson (Z., C.), Thomas Poole (P.), Robert Scott Reid (C.), Francisco Ribeiro (P., C.), Andrew Riddell (B., P.), Samuel Murdoch Riddick (Z.), Humphrey Robertson (Z., C.), John Joseph Robertson (B., Z., P.), Frederick [illegible]
[illegible] Hugh Stewart (P., C.), Henry Stuart
(Z.), Herbert Arnold Summers [illegible] (Z., C.),
Joseph Turner Taylor (B., P.), [illegible], Robert
Nisbet Walker (Z., C.), William [illegible], James
Watt (Z.), John Pendleton Whi [illegible] (B., Z.,
P., C.), George Young (Z., C.), Robert Young (P.), and William Young (Z., C.).

Women.—Janetta Margaret Alexander (P.), Annetta Gillies Turnbull Anderson (Z., C.), Marjorie Mason Anderson (Z., C.), Jean Mary Frew (Z., C.), Margaret Hutchison Glen (Z., C.), Alison Mary Hunter (Z.), Grace Leisk Hunter (Z., C.), [illegible]
Leitch (B.), Elizabeth Clark M'Haffie, M.[illegible]
Mackinnon (Z., C.), Jessie Brown Maclachl[illegible]
(Z., C.), May Isabella Turner Reid (Z., C.). [illegible]
(Z., C.), Margaret Nelson Robertson (Z.), [illegible]
(P., C.).

The following have passed in the subjects indicated (A., anatomy; P., physiology; M., materia medica and therapeutics) the Second Professional Examination (Old or New Ordinance), or the Third Professional Examination (New Ordinance) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

Ismail Abdurahman (A.), Robert Aitken (A., P.), William Allan (M.), Robert Mitchell Stewart Boyd (P.), William Ernest Boyd, M.A. (M.), John Bradford (M.), Donald Campbell Buchanan, M.A. (P.), John Buchanan (A.), William Edmund Alexander Buchanan (M.), Donald Ronald Colin Cameron (A., P.), John Cameron (A., M.), Dugald Stewart Campbell (A., P.), John Munro Campbell (M.), Moses Wolffe Cantor (A., P.), Alfred Mackenzie Clark (M.), Allan La Barte Clark (P.), John Connal (P.), Robert Stobo Crawford (P.), Henry Paterson Crow (A., P.), William Cunningham (A., P., M.), William Donald (P.), Alexander Hogg Donaldson (A., P., M.), Ernest M'Murchie Dunlop (A., P.), Thomas Ferguson (P.), Harry Taylor Findlay (M.), Robert Forbes (A., P., M.), George John Fraser (A., P.), Walter Weir Galbraith (M.), Leonard Woodburn Gemmell (P.), Robert Stuart Gibson (A., P.), *John Gilchrist* (A.)., *Robert Kinnear Hay Gillespie* (A., P.), Colin Campbell Blair Gilmour (A., P., M.), John Glaister (P.), William Gordon (A., P.), Ronald Thomson Grant [illegible]
[illegible] n (A., P., M.), William Allan Higgins,
[illegible] M.), George Kirkhope (A., P.), John
[illegible] Kyle (A., P., M.), Hugh Brown Lawrie
[illegible] Leiper (A., P.), Alfred Thomas Logan
(A., P.), Peter Young Lyle (A., P.), Reginald Lyon (P.), Hugh Lawrence M'Cormick (P., M.), Hugh Douglas M'Crossan (P.), Archibald Munn M'Cutcheon (M.), Duncan Fraser Macdonald (M.),
[illegible] (M.), David M'Farlane (A., P., M.), John
[illegible]), Gerald James M'Gorty (A., M.), Archi-
[illegible], Alexander Fraser M'Intosh (A., P., M.),
James Murdoch Mackay (M.), George Maclean (A., P., M.), Peter Donald MacLean, M.A. (A., P., M.), Malcolm Bonar Macleod (A., P., M.), David M'Neill (P.), William Martin (P.), James M'Donald Matheson (M.), John Campbell M'Intyre Matheson (P., M.), Thomas Duff Miller (A., P., M.), John Desmond Milligan (A., P., M.), Peter Orr Moffat (P., M.), Laurence Sebastian Morgan (A., P., M.), *Noah Morris* (A., P.), *Frederick William Morrison* (A., P., M.), Hugh Adam Munro (A., P., M.), Prem Nath (M.), William O'Brien (A., P., M.), Michael O'Callaghan (A.), James Alphonsus O'Connor (M.), Arthur William Panton (A., P., M.), John Roberts Pate (A., P.), James Paterson (A.), James Herbert Paul, M.A. (A., P., M.), William James Poole (M.), William Burns Primrose (M.), Hugh Quigley (M.), John King Rennie (A., P.), James Richardson (P.), David Bell Robertson (M.), George William Ronaldson (A., P.), Kenneth M'Alpin Ross (A., P., M.), William Jack Scade (A., P., M.), Seymour Cochrane Shanks (M.), William Frederick Shanks (M.), John Sillars (A.), James Tait Smith (A., P., M.), John Smith, M.A. (P.), Andrew Stenhouse (A., P.), John Stirling (A., P.), Robert Sutherland Strachan (M.), Robert Taylor (A., P., M.), Cecil Raymond Tytler Thompson (P.), Robert Taylor Todd (A., P.), Adrian Johannes Van der Spuy (A., M.), George Turnbull Walker (M.), James *Walker (M.), James Gordon Wilson* (A.), Thomas M'Skimming Wilson (P.), Alexander Young (P.), and Thomas Young (A., P., M.).

Women.—Jane Beattie Davidson (A.), Janet Fraser Henderson (A.), Helen Isobel Winifred Kerr (M.), Dorothy M'Cubbin (M.), Margaret Jane Maclachlan (P.), Mary Anderson Noble (P.), Mary Scott (A.), Margaret Ann Hendry Stewart (A., P.), Isabel Stirling Thomson (A., P.), Margaret Walker (M.), Mary Ferguson Wood, M.A. (P.), and Isabella Henrietta Younger (M.).

The following have passed in the subjects indicated (P., pathology; M., medical jurisprudence and public health), the Third Professional Examination (Old and New Ordinance), for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

George Kirkwood Allan (P.), James Mair Anderson (P.), John Anderson (M.), Robert Armstrong (P., M.), George Fleet Barr (P., M.), Andrew Duffield Blakely (P.), Robert William Brander (P., M.), William Hunter Brown (P., M.), Maurice Smith Byrce (P., M.), Samuel Bryson (P.), James Alexander Chrystie (M.), Robert Clark, M.A. (P.), Andrew Climie (P., [illegible]

UNIVERSITY OF DURHAM.—At the Convocation [illegible]d on March 29th the following degrees and diplomas were [illegible]ffirmed:—

[illegible]

[illegible]aster of Surgery (*M.S.*) [illegible]

[illegible]achelor of Medicine [illegible] Burrell, B.Sc., Willi[illegible] [illegible] Stanley Arkle, Theonie Renée Burrell, B.Sc., [illegible] Frederick Joh[illegible] Charles Henry [illegible] Newcastle-upon[illegible] College, London.

[illegible]achelor of Hygiene (*B.Hy.*).—Patrick Albert Galpin and William Hudson.

[illegible]ploma in Public Health (*D.P.H.*).—Patrick Albert Galpin and William Hudson.

[illegible]icence in Dental Surgery (*L.D.S.*).—George Vernon Watt, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*[illegible]giers* (*Medical School*): Dr. Poujol has been appointed to [illegible] chair of Pathological Anatomy.—*Bologna*: Dr. Pazzi, [illegible] Genoa, has been recognised as *privat-docent* of Mid[illegible]ery and Gynæcology, and Dr. A. Ghedni as *privat-[illegible]ent* of Operative Medicine.—*Bonn*: Dr. Karl Bachem, *[illegible]vat-docent* of Pharmacology, Dr. Hugo Stursberg, *privat-[illegible]ent* of Medicine, and Dr. Erich Zurhelle, *privat-docent* of [illegible]næcology, have been granted the title of Professor.—*[illegible]ston* (*Harvard University*): Dr. Richard P. Strong has [illegible]n appointed to the chair of Tropical Diseases.—*[illegible]eslau*: Dr. F. Henke, of Königsberg, has been appointed [illegible] the chair of General Pathology and Pathological Anatomy, [illegible] succession to Dr. Ponfick, resigned.—*Catania*: Dr. [illegible] D'Urso has been recognised as *privat-docent* of Anatomy, [illegible] Dr. G. Zurria as *privat-docent* of External Patho[illegible]y.—*Düsseldorf* (*Academy of Practical Medicine*): Dr. [illegible] G. Mönckeberg, extraordinary professor of Patho[illegible]ical Anatomy in the University of Giessen, has been [illegible]pointed Director of the Municipal Pathological Institute and [illegible]mber of the Faculty of the Academy, in succession to Dr. [illegible] Lobarsch, who goes to Kiel.—*Halle*: Dr. Aichel has been [illegible]ognised as *privat-docent* of Anatomy, and Dr. F. Lehnerdt [illegible] *privat-docent* of Pædiatry.—*Heidelberg*: Dr. F. Lust has [illegible]n recognised as *privat-docent* of Pædiatry.—*Kiel*: Dr. [illegible]x Kappis has been recognised as *privat-docent* of Surgery. [illegible] *Königsberg*: Dr. F. B. Hofmann, professor in Prague, has [illegible]n appointed to the chair of Physiology, in succession to [illegible]. Hermann, resigned; Dr. Hans Reiter has been recognised [illegible] *privat-docent* of Hygiene and Bacteriology.—*Lausanne*: [illegible]. H. Vulliet, *privat-docent* of surgery, has been promoted [illegible] Extraordinary Professor.—*Lemberg*: Dr. G. Bikeles, *privat-[illegible]ent* of neurology, has been granted the title of Ordinary [illegible]fessor.—*Lille*: Dr. Lambert has been appointed to the new [illegible]air of Clinical Surgery.—*Marburg*: Dr. Jores, of the Cologne [illegible]ademy of Practical Medicine, has been appointed to the [illegible]air of Pathological Anatomy, in succession to Dr. Martin [illegible] Schmidt.—*Montevideo*: [illegible] [illegible]n appointed to the chair of [illegible] [illegible]ver has been appointed Pro[illegible] *Naples*: Dr. Raffaeli Lettieri and Dr. Ignazio Scalone have been recognised as *privat-docenten* of External Pathology.—*Pavia*: Dr. F. Marcora has been recognised as *privat-docent* of Medical Pathology; and Dr. G. Verdelli as *privat-docent* of Midwifery and Gynæcology.—*Philadelphia* (*Medico-Chirurgical College*): Dr. Ross H. Skillern has been appointed Professor of Laryngology in succession to Dr. Cleveland.—*Philadelphia* (*Women's Medical College*): Dr. Randle C. Rosenberger, of Jefferson College, has been appointed Professor of Hygiene.—*Prague* (*German University*): Dr. R. Schmidt, professo[illegible] chair of Medicin[illegible] *Rio de Janeiro*: [illegible] to the chair of Clinical Neuroses.—*Rome*: Dr. R. Dalla Vedova, of Modena, has been appointed Extraordinary Professor of Orthopædic Surgery.—*Rostock*: Dr. M. Wirths has been recognised as *privat-docent* of Ophthalmology, and Dr. A. Burchard as *privat-docent* of Radiology.—*San Paulo*: Dr. Ficker, of the Hygienic Institute, Berlin, has been appointed to take temporary charge of the Municipal Bacteriological Institute, having obtained a year's leave from Berlin for that purpose.—*Vienna*: Dr. von Ebner, [illegible] Children's Diseases.—*Wurzburg*: Dr. Martin B. Schmidt, of Marburg, has been appointed Professor of Pathological Anatomy in succession to Dr. Kretz, resigned.

METROPOLITAN POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association was held at Frascati's Restaurant on April 2nd. Mr. Meredith M. Townsend was elected president for the coming year, and Dr. G. A. Hamerton vice-president. Dr. C. Owen Fowler and Dr. G. Nicol Henry, the honorary secretaries, received the thanks of all the members for the way in which they had fulfilled their arduous duties, and were unanimously requested to continue in office. Mr. H. Bott was re-elected honorary treasurer, and the six vacancies on the council were filled by the election of Mr. A. E. Kennedy, Dr. G. B. Scott, Mr. C. T. W. Hirsch, Dr. W. A. Rudd, Dr. W. R. Burgess, and Mr. Percy Clark. The meeting was followed by the annual dinner, which was under the chairmanship of the President (Mr. Victor A. Jaynes), [illegible] Paul Taylor, one of the metropoli[illegible] [illegible]. C. A. Ballance, M.V.O., the new [illegible]ldie, one of the coroners for the C[illegible] [illegible]. H. Tripp, the Receiver for the Metropolitan Police District. After the usual loyal toasts had been honoured, Mr. Taylor, in a humorous speech, proposed "The Metropolitan Police Surgeons' Association." He remarked on the many links of common interest there were between magistrates and police surgeons, and what a help the latter were to him in his work, and how he, in spite of the allurance of advocacy, was always guided by the opinion of the divisional surgeon, which always gave a correct summary of the situation without flowery language, though he had a recollection of one member who generally certified cases of alcoholism as "stinking drunk." Dr. R. Esler gave the toast of "The Commissioners and the Receiver," which in the unavoidable absence of Sir Frederick Wodehouse, K.C.V.O., was replied to by Mr. Tripp, to whom Dr. Esler had facetiously referred as the official enemy, but actual friend of all police surgeons, even in the matter of special fees. Dr. Fowler proposed "The Chief Surgeon" and feelingly mentioned the late chief surgeon, Mr. Clinton Dent, and the many benefits divisional surgeons now enjoy which were brought about through the instrumentality of the late Mr. Dent, whose personal charm and record of work would always be remembered and would be a stimulant and encouragement to his distinguished successor, to whom the association extended a very hearty welcome and hoped that the friendly relationship of the past between the chief surgeon and divisional surgeons would be continued in the future. Mr. Ballance made a most interesting reply. Mr. Bott, in an entertaining speech, expressed the satisfaction all felt at seeing the guests, which was responded to by Mr. Arthur Denman, who feelingly gave a reminiscence of how a client he had defended, in obtaining some boots, had disarranged a constable's buttons, and how the secretary of the association had attended in court regarding the matter. Between the toasts Miss Ethel Williams, Miss Margaret Crawford, Mr. Walter Dennis, and

Mr. William Cox added to the enjoyment of the company by their excellent rendering of songs.

THE DUTY AND DISCIPLINE MOVEMENT.—A meeting will be held to-day (Friday, April 11th) at 5.15 P.M. at Caxton Hall, Westminster, S.W., under the presidency of Professor Robert Saundby, M.D., when Dr. Eric L. Pritchard and Mr. Alfred F. Tredgold will speak on Self-development and National Health.

CHELSEA HOSPITAL FOR WOMEN.—The annual meeting of the governors of this hospital was held on April 3rd, the President, Viscount Castlereagh, in the chair. The council's report showed that satisfactory progress had been made during 1912 in the collection of funds for the rebuilding of the hospital and its nurses' home on the site so generously given by Earl Cadogan. Through the dinner at which Viscount Castlereagh and the Countess of Ilchester, the president of the ladies' committee, had jointly presided in November, over £8000 was added to the amount available. Nearly £500 was sent in small amounts from former patients. King Edward's Fund had made a first grant of £1000. The medical work was again excellent; of the 885 in-patients, 516 had needed operative treatment of a critical nature, but the rate of mortality was only 1½ per cent.

WEST END HOSPITAL FOR NERVOUS DISEASES.—The annual meeting of this hospital was held last week, Mr. Leonard Brassey, M.P., being in the chair. Although the subscriptions and donations during 1912 had somewhat fallen off, yet patients' payments, dividends, and legacies all showed increases, and the total income amounted to some £350 more than that of 1911. The total expenditure also showed a small increase, owing to some extraordinary charges which had to be included this year. The average weekly cost per in-patient was less than in the previous year by 4*s.* 5*d.*, and the cost per out-patient attendance was also reduced. In-patients under treatment numbered 319; but there is a very long list of patients awaiting admission, amounting in the case of women to four or five for each bed. The provision of extra accommodation is most urgently needed, and an appeal is made for donations to wipe off the £5000 debt, so that a scheme of extension may be taken in hand.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—The annual meeting of the above society will be held at 1, Wimpole-street, London, W., on Thursday and Friday, April 24th and 25th, 1913. The morning sessions will be from 10.30 to 12.30 and the afternoon from 2.30 to 4.30. On Thursday morning, April 24th, at 1, Wimpole-street, the following papers will be read:—Mr. Frank Juler: Acute Purulent Keratitis in Exophthalmic Goitre treated by Repeated Tarsorrhaphy. Mr. Ormond: Two cases of Permanent Hemianopia following Migraine. Dr. Taylor and Dr. Gordon Holmes: (*a*) Conditions Present in Several Members of a Family with Hereditary Optic Atrophy; (*b*) Unusual Conditions Associated with Optic Atrophy of the Family Type. Mr. Bishop Harman: (*a*) An Analysis of 250 Cases of High Myopia; (*b*) A Suggestion for the Grading of Fundus Changes in Myopia. On Thursday afternoon, April 24th, at 1, Wimpole-street, the following papers will be read:—Mr. Angus Macnab: An Operation for the Excision of the Conjunctival Sac and Lid Margins. Mr. Dorrell: Sensory Reflex in Tobacco Amblyopia. Mr. Treacher Collins and Mr. Hudson: On the Pathological Examination of an Eye with Congenital Anterior Staphyloma. Mr. Treacher Collins: Visible Vessels on the Surface of the Iris. The annual business meeting will be held at the conclusion of the afternoon meeting on Thursday. On Friday morning, April 25th, at 1, Wimpole-street, W., there will be a discussion on Vascular and other Retinal Changes in Association with General Disease, to be opened by Dr. James Taylor, Dr. Louis Werner, and Mr. George Coats. On Friday afternoon, April 25th, at 2.30, the society will meet at the Royal London Ophthalmic Hospital, City-road, E.C., when the following cases and others will be shown:—Mr. Angus Macnab: An Early Case of Chronic Glaucoma Operated on by Trephining, in which there was subsequently a diminution in the excavation of the disc. Mr. Treacher Collins: A case of Buphthalmos with Full Vision and without any cupping of the optic disc. Mr. Ormond: (*a*) Thrombosis of the Retinal Veins, shown at a meeting of the Ophthalmological Society in October, 1906; (*b*) case of Albuminuric Retinitis of ten years' standing. Mr. Lawford: Vascular and Retinal Changes resulting from Partial Venous Thrombosis. A discussion will follow the examination of the cases. An exhibition of ophthalmic instruments, &c., will be held during the days of the meetings at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., to which all members are invited.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk and Dairies (Scotland) Bill.

THE Milk and Dairies (Scotland) Bill, which was recently introduced in the House of Commons by Mr. MCKINNON WOOD, the Secretary for Scotland, is designed to "ensure the purity of milk supplies and to regulate dairies in Scotland and for other purposes connected therewith."

As stated in a memorandum, the main objects of this Bill are to provide for—

1. The appointment by local authorities of a veterinary inspector.
2. The inspection of dairies, and of the cattle therein.
3. The registration of dairies.
4. The provision of by-laws for—
   (*a*) the inspection of cattle;
   (*b*) the construction, &c., of dairies;
   (*c*) the prevention of impurities in milk, and the cleanliness of persons engaged in dairy business;
   (*d*) the precautions to be taken by dairymen against infection.
5. The issue of regulations by the Local Government Board for Scotland for—
   (*a*) the prevention of danger to public health from the importation of milk, butter, and cheese; and
   (*b*) securing the supply of pure and wholesome milk.
6. The prohibition of the supply of milk which has caused or is likely to cause infectious disease.
7. The establishment by local authorities of milk depôts for the sale of milk specially prepared for infants.

The provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts, and the Orders made thereunder. The provisions as to the inspection of dairies and prohibition of the supply of milk are an extension of those contained in Sections 60 and 61 of the Public Health (Scotland) Act, 1897. The Board of Agriculture and Fisheries have issued an Order under the Diseases of Animals Act, 1894, dealing with tuberculous cows, and providing for the payment of compensation in cases of slaughter. The Treasury are prepared, subject to the assent of Parliament, to sanction the payment from the Exchequer of one-half of the net amount paid by way of compensation for a period of five years.

Medical Attendance under the Insurance Act.

It is expected that on Wednesday, April 30th, the House of Commons will discuss a motion dealing with the administration of the Insurance Act and medical benefit.

Vaccination Acts (Repeal) Bill.

Amongst the Bills recently introduced in the House of Commons is one "*to repeal the Vaccination Acts, 1867 to 1907.*" It was presented by Mr. BLACK.

Select Committee on Patent Medicines.

The Select Committee of the House of Commons on Patent Medicines heard further evidence on Thursday, April 3rd, on behalf of the owners of proprietary remedies.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 2ND.

Aged Members of Friendly Societies.

Captain FABER asked the Secretary to the Treasury whether anything was to be done to prevent members of Friendly Societies of over 65 years of age being compelled to pay increased contributions for medical attendance and treatment.—Mr. MASTERMAN replied: I have nothing to add to the answers which I have already given on this subject.

Mr. W. CROOKS: May I ask whether the subject might be reconsidered in the interest of the old people?—Mr. MASTERMAN: Certainly, the understanding was that these people would receive medical attendance and treatment on the terms which the Friendly Societies now offer.

Captain FABER: With whom was the understanding made?—Mr. MASTERMAN: With representative members.

Mr. O'GRADY: Was this statement based on the assumption that the fees to be paid to medical men would be less than the amount which was afterwards agreed to be paid?—Mr. MASTERMAN: That is exactly true. They were willing to take the people for 6*s.* The societies are now offering 6*s.*, which is 2*s.* more than they used to pay.

Mr. WORTHINGTON EVANS: Is it not intended that the members of Friendly Societies who are not within the Act should have exactly the same treatment as those who are within the Act?—Mr. MASTERMAN: At a reasonable figure. The fact that we are giving half-a-crown overnment subsidy more than for the others would, I should have hought, have made the doctors more willing to take these patients.

Medical Benefit and Migratory Insured Persons.

In reply to Viscount **WOLMER**, Mr. **MASTERMAN** said: An insured ervant who moves from one area to another may, by giving notice to

Medical Certificates for Sickness Benefit.

In answer to Sir WILLIAM BULL, Mr. J. M. ROBERTSON (on behalf of the Secretary to the Treasury) said that the acceptance or refusal of a certificate of any particular medical practitioner for the purpose of [illegible] was in the first instance for the Approved [illegible] a right of the insured person to appeal to [illegible] under Section 67 of the National Insurance Act. It was not the case that the Government auditors would look to the secretary of an Approved Society to refund money paid on the certificate of non-panel medical men as having been money unlawfully paid away.

Supply of Drugs for Insured Persons.

Mr. KING asked the Secretary to the Treasury whether he was aware of the offence proved against a firm of chemists in Staffordshire, who sold to an Insurance Committee a number of pills not in accordance [illegible] hether Insurance Committees were empowered [illegible] ny chemists convicted of such offences; and [illegible] Commissioners would occasionally test the medicines and pills supplied and so ensure their proper composition and efficacy.—Mr. J. M. ROBERTSON (on behalf of Mr. MASTERMAN) replied: The Commissioners have seen a report of the case referred to. If any representations are made to them that the inclusion or continuance on the panel of any chemist will be prejudicial to the efficiency of the service they may, after inquiry, exclude or remove such chemist from the panel. With regard to the third part of the question, it is the duty of the Insurance Committee to take such steps as may be necessary to secure a proper and efficient supply of drugs and medicines for the insured persons in their area.

Unsatisfactory Housing Conditions in Hitchin.

Replying to Sir HENRY HAVELOCK-ALLEN, Mr. BURNS (President of the Local Government Board) said: I am aware that in some parts of the urban district of Hitchin the housing conditions are very unsatisfactory, and I have for some time past been in correspondence with the district council in relation to the Queen-street [illegible] a view to action being taken by the council to [illegible] that area by making an improvement scheme [illegible] Working Classes Act, 1890. I have addressed a further letter to the council on the subject.

TUESDAY, APRIL 8TH.

Medical Treatment of School Children in Scotland.

Replying to Mr. JAMES HOGGE, Mr. MCKINNON WOOD (Secretary for Scotland) said: The only legislation which I contemplate for this session in connexion with the Education Acts is a Bill to give additional power to the school boards to provide for medical treatment in Scotland.

WEDNESDAY, APRIL 9TH.

Arrangements for Medical Treatment under the National Insurance Act.

Mr. NEWMAN asked the Chancellor of the Exchequer whether it had been brought to his notice that Insurance Committees, in refusing applicants desirous of making their own medical arrangements, were in the habit of assigning no reason for their inability to comply with the request of the insured person, but merely warned the applicant that, failing making a selection by March 31st, he would be liable to distribution among doctors on the panel; and whether, in view of the [illegible] was considered on its merits, he would explain [illegible] was not stated in the reply.—Mr. ROBERTSON [illegible] lor of the Exchequer) replied: An Insurance [illegible] obligation to explain in each individual case the reasons for refusing an application from an insured person for permission to make [illegible] endance and treatment. The [illegible] g the Insurance Committees [illegible] cated in the memorandum on [illegible]

Spezielle Chirurgische Diagnostik. Für Studierende und Aerzte. Bearbeitet von Dr. F. de Quervain, O. O. Professor der Chirurgie und Direktor der chirurgischen Universitätsklinik in Basel. Vierte, vervollständigte Auflage. Price, paper, M. 18; bound, M. 20.

Appointments.

Successful applicants for V[illegible] Public Institutions, and others possessing [illegible] this column, are invited to forward to [illegible] cted to the Sub-Editor, not later than [illegible] morning of each week, such information [illegible]

BLOOM, A., M.B., Ch.B. Edin., has been appointed House Physician at the Hampstead General Hospital.

BOYD, F. D., C.M.G., M.D. Edin., F.R.C.P. Edin., has been appointed Physician to th[illegible] Infirmary.

CARRICK, JAMES, [illegible] en appointed Assistant Medical Officer [illegible] Paisley.

COMRIE, J. D., [illegible], has been appointed Assistant Physician to the Edinburgh Royal Infirmary.

ERL[illegible] Edin., has been appointed House Surgeon [illegible] al Hospital.

FRE[illegible] F.R.C.S. Edin., has been reappointed [illegible] tol General Hospital.

GRAHAM, LEWIS, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Honorary Surgeon and Registrar to the Birmingham and Midland Hospital for Women.

[illegible] D.P.H., has been appointed Medical Officer [illegible] of Mansfield, Notts.

[illegible] has been appointed Visiting Physician [illegible] Glasgow.

MCNAIR, A. J., M.B., B.C., has been appointed Clinical Assistant to the Chelsea [illegible]

MANSFIELD, [illegible] on., has been appointed Certifying Surgeon [illegible] Workshop Acts for the Sevenoaks District of the county of Kent.

MORTON, C. A., F.R.C.S. Eng., has been reappointed Surgeon to the Bristol General Hospital.

OSMOND, CHARLES HOLDWAY, L.F.P.S. Glasg., L.S.A. Lond., has been appointed Medical Officer to the Ilfracombe District by the Barnstaple (Devon) Board of Guardians.

PARKIN, ALFRED, M.D. Durh., F.R.C.S. Eng., M.R.C.P. Lond, has been appointed Honorary Physician to the Royal Victoria Infirmary, Newcastle-on-Tyne.

ROWNTREE, CECIL, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Surgeon to the St. Marylebone General Dispensary.

ROY, DONALD W., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Samaritan Free Hospital for Women.

STEPHENSON, SYDNEY, D.O. Oxon., has been appointed Ophthalmic Surgeon to King Edward Memorial Hospital, Ealing, W.

STOPFORD, J. S. B., M.B., Ch.B. Manch., has been appointed Senior Demonstrator of Anatomy in the University of Manchester.

STRACHAN, G. I., M.B., Ch B. Glasg., has been appointed House Physician at the Bristol Royal Infirmary.

SUTCLIFFE, W. H., L.K.Q.C.P.I., L F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Lisbellaw District of the county of Fermanagh.

WALLACE, J. M., M.R.C.S., L.R.C.P.Lond., has been appointed Assistant Casualty Officer at the Camden Town Branch of the Hampstead General Hospital.

WATSON, J. K., M.D., C.M.Edin., has been appointed Certifying [illegible]

[illegible] Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

[illegible] washing.

[illegible] —Assistant [illegible] six months. [illegible] lodging, and washing.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN.—House Surgeon, unmarried, for six months. Salary £80 per annum, with apartments, [illegible]

[illegible] urgeon. [illegible] House [illegible] lary £80 [illegible] House [illegible] m, with [illegible] Officer [illegible] board, [illegible] Second [illegible] uarters, [illegible] se Phy- [illegible] tments, board, and laundry.

[illegible] Officer, unmarried. [illegible] washing, and [illegible] Officer. Salary [illegible]

[illegible] M, Garlands.— [illegible] er annum, with [illegible]

[illegible] Physician. [illegible] ndry. [illegible] l Assistant [illegible], with board, [illegible] geon. Salary £100 [illegible] it House Surgeon, [illegible] n, with board and laundry.

DORCHESTER, DORSET COUNTY ASYLUM.—Third Assistant Medical [illegible]

[illegible] Officer in Kings- [illegible] Surgeon for six [illegible] ence, board, and washing.

[illegible] £120 per annum, [illegible] Salary at rate [illegible] Assistant House [illegible] per annum, with board, apartments, and washing.

EXMINSTER, DEVON COUNTY ASYLUM.—Fourth Assistant Medical Officer. Salary £130 per annum.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary [illegible]

GRE [illegible]

HAL [illegible] washing.

HASTINGS, EAST SUSSEX HOSPITAL.—Senior House Surgeon. Salary £100 *per annum, with residence, board, and washing. Also* Assistant House Surgeon. Salary at rate of £70 per annum, with [illegible]

[illegible] —Third Assistant Medical [illegible] nnum, with board, apart- [illegible]

[illegible] PITAL.—Resident Medical [illegible] ooms, board, and washing.

[illegible] mond-street, London, W.C.— [illegible] unmarried, for six months.

HUI [illegible] o Surgeon. [illegible] ng.

INF [illegible] ASYLUMS [illegible] Salary £180 per annum, with board, lodging, and washing.

LEAMINGTON SPA, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL AND MIDLAND COUNTIES BATHING INSTITUTION.—House Physician. Salary £85 per annum, with board, residence, and laundry.

LEEDS GENERAL INFIRMARY.—Resident Obstetric Officer for six months. Salary £50 per annum, with board, residence, and laundry. Also Two House Surgeons without salary, but with board, residence, and laundry.

L [illegible] Honorary Surgeon and Assistant [illegible] ant House Surgeon and Assistant [illegible] Salary at rate of £30 per annum, with board, apartments, and washing.

LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary £100 per annum, [illegible]

LIV [illegible] geon. Salary £75 per [illegible]

MAC [illegible] Parkside.—Temporary [illegible] months. Salary £4 4s. per week, with apartments, board, and washing.

[illegible] Medical Assistant. [illegible] washing.

[illegible] AND CHILDREN, [illegible] Junior House [illegible] respectively, with apartments and board.

MANCHESTI [illegible] dical Officer in Aural Departı [illegible]

MANCHESTI [illegible] Assistant Medical Officer, [illegible], with rations, apartments, [illegible]

METROPOLI [illegible] E.—Pathologist and Registr [illegible] nnum. Also House Physician, House Surgeon, Assistant House Physician, and [illegible]

[illegible] £50 per annum.

NEWCASTLE-ON-TYNE DISPENSARY.—*Vacancies on the Visiting Medical* Assistants' Staff. Salary £160 per annum.

NEWCASTLE-ON-TYNE HOSPITAL FOR SICK CHILDREN.—Junior House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, residence, and laundry.

Willesden Urban District Education Committee.—Treatment of Cases of School Children suffering from Ringworm. Salary £100 per annum.

Winchester, Royal Hampshire County Hospital.—House Surgeon. Salary £80 per annum.

Wisbech, North Cambridgeshire Hospital.—Resident Medical Officer. Salary £150 per annum, with unfurnished house, free of rent and rates.

Wolverhampton and Staffordshire General Hospital.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Lochee, in the county of Forfar; at Clwtybont, in the county of Carnarvon; and at Sileby, in the county of Leicester.

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Counties of Elgin and Nairn.

Births, Marriages, and Deaths.

BIRTHS.

Ellis.—On March 30th, at Maple-road, Bournville, Birmingham, the wife of F. W. Ellis, M.D., F.R.C.S., of a son.

Highet.—On April 3rd, at Bangkok, Siam, the wife of H. Campbell Highet, M.D., D.P.H., Principal Medical Officer, Local Government, of a son.

Thompson.—On April 4th, at Tutshill, Chepstow, to the wife of Cecil C. B. Thompson, M.R.C.S., L.R.C.P., a daughter.

Wheeler.—On April 5th, at North-street, Rugby, the wife of J. Norman Wheeler, M.B., B.C., of a daughter.

Witney.—On March 31st, at Cromwell House, Whitstable, to Dr. and Mrs. Witney, a son.

MARRIAGES.

Dee—Kelly.—On April 2nd, at the Catholic Church, Clacton-on-Sea, Joseph Patrick Dee, M.D., to Margery, eldest daughter of M. S. Kelly, Walton-on-Naze.

Forster—Rowe.—On April 3rd, at St. James's, Piccadilly, Charles Michael Forster, B.A. Cantab., M.R.C.S., L.R.C.P., to Mary Margaretta, second daughter of the late Almond Rowe, Straits Settlements Civil Service.

West—Finchett.—On April 3rd, at All Saints', Margaret-street, W., by the Rev. Wilfrid Moor, Henry Owen West, M.D., eldest son of the Rev. John O. and Mrs. West, of Wednesbury, to Annie, third daughter of the late William Henry Finchett and Mrs. Finchett, of Chester.

DEATHS.

Dawson.—On April 1st, from heart failure and pneumonia, Rankine Dawson, M.D., aged 55.

Harvey.—On April 4th, at Headley, Hants, after much suffering, Emily Margaret Viola, aged 21 years, only daughter of Sidney Harvey, 117a, Queen's-gate, S.W. Indian and colonial papers please copy.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC-HOUSE REFORM.

In The Lancet of Oct. 19th, 1912, we called attention to a little pamphlet on the Public-House Trust, an organisation having for its object the checking of intemperance by elevation of the status and morals of the public-house, by restoring it to its proper place as a house of refreshment rather than a mere drinking shop. We have now before us a book entitled "Public-House Reform," issued by the People's Refreshment House Association, of Broadway Chambers, Westminster, both the book and the institution having a kindred purpose to that of the Public-House Trust. The association, which was registered under the Industrial and Provident Societies Act, 1893, was founded by Colonel Craufurd and the Bishop of Chester in 1896, and has for its object the acquiring of suitable public-houses and the placing of them under the charge of its own managers. The houses are conducted on the lines of respectable houses of refreshment instead of as mere drinking bars; food and non-intoxicants are exposed for sale on an equal footing with intoxicants. The manager is relieved from any temptation to push the sale of intoxicants from the fact that he is charged the full retail price for all alcoholic drinks consumed, whereas he is supplied with non-alcoholic drinks and food at a wholesale rate, which enables him to make a profit thereon. Great care is taken to avoid the adulteration of liquor. The invested capital is entitled out of profits to a dividend not exceeding 5 per cent. per annum, any surplus, after providing for a reserve fund, being devoted to objects of public utility, local or general. The first inn taken over was one at Sparkford, Somerset, in October, 1897. The growth of the association may be seen in the fact that whereas at the beginning of 1901 it controlled 14 houses, it now controls 113. The maximum dividend has been earned continuously since 1899, the assets have increased from £3500 to nearly £100,000, and the reserve fund stands at £3600. Every house has a comfortable tea-room distinct from the bar, and most have tea-gardens, many of them having also well-furnished bedrooms. There are, of course, no "tied" houses There are frequent inspections at irregular intervals, and while prominent attention is called by notices to non-alcoholic beverages and foods, no advertisement of intoxicating liquors occurs except in the necessary price lists. A perusal of the instructions to managers indicates the great care taken to maintain the supremacy of the purposes for which the association exists, and there is abundant testimony forthcoming of the elevating tendency of the work in those districts where it is in operation. The book contains a list, by counties, of the inns and hotels under the association's management, with particulars of the house and neighbourhood, and distance from the nearest station, and the pictures of many of them make quite an attractive appearance. The statement is made that "It is quite obvious that public-houses will always be with us, and the principal question is therefore whether they shall be conducted on a good or a bad system," and since experience proves that the reduction of public-houses is generally followed by the rise of drinking clubs, which cannot be easily controlled, there seems little doubt that this and the kindred associations, of which there are several, catering especially to the particular local needs of different districts, are deserving of every support.

"THE RISING OF THE LIGHTS."

To the Editor of The Lancet.

Sir,—May I refer "G. S. M" and the author of your annotation on Enterotaxis to Graunt's "Observations on the Late Bills of Mortality." This little book was first published, I think, in 1662. In it will be found the statement that there had recently appeared in England two new and fatal diseases, "the Rising of the Lights and the Stopping of the Stomach." The association suggests the symptoms of eructation and distension. The term "rising of the lights" was, I believe, applied to any grave disorder of unknown origin in which these symptoms were prominent. The suggested pathology was, of course, based on an erroneous conception.

The book itself is otherwise of interest as one of the earliest contributions in this country to the science of statistics. It contains several remarkable passages, among them a prophecy of the industrial revolution to follow the widespread use of "stone-coal." The author also sets forth observations on and deductions from the rapid growth of London, where already, at that early date, Ludgate Hill is described as "a throat too strait for the body."

All the above is quoted from memory, as I cannot here consult either the work itself or references to it. The identity, however, of this writer on the "rising of the lights" is still, I believe, uncertain. Graunt was one of the early Fellows of the Royal Society and is mentioned by contemporary writers, including both Pepys and Evelyn. In Evelyn's

Diary, in the entry for March 22nd, 1675, is a delightful description of a supper at the house of Sir William Petty. Evelyn gives an account of Petty's life, terminating with the remark: "He [Petty] is the author of the ingenious deductions from the bills of mortality which go under the name of Mr. Graunt. .... He was also author of that paraphrase on the 104th Psalm in Latin verse which goes about in MS. and is inimitable. *In a word, there is nothing impenetrable to him.*" Burnet also remarks (*"Own Times," Vol. I., p 401, ed. 1823) that* "Sir William Petty published his Observations on the Bills of Mortality in [illegible] abilities. He was the author of the "Political Arithmetic," and was the father of statistical science. That study, however, formed but a fraction of his activity. Thus he was professor of anatomy at Oxford and of music at Gresham College! Later he became physician to the *army in Ireland, and he subsequently took part in the Commission for* the division of the lands forfeited by the Irish rebels. Manuscripts in Petty's handwriting relating to this Commission have, I believe, been presented to Oxford University by Sir William Osler, who recently read a paper on Petty before the Historical Section of the Royal Society of Medicine (THE LANCET, Nov. 30th, 1912, p. 1504).

It would be interesting to know whether any reference to the "rising of the lights" earlier than that of *Petty* or *Graunt is known to your* readers. I am, Sir, yours faithfully,

Heidelberg, March 31st 1913. CHARLES SINGER.

To the Editor of THE LANCET.

SIR,—If "Rising of the Lights" as a popular phrase stands for "dyspepsia" in Lancashire, or for "emphysema" or "displacement of organs" in Scotland or other places where the masses may be *scientifically educated, in London it stands, or at least used to stand,* for "profuse expectoration" or "a power of *spit.*" (Spitalfields, the parish of Dr. H. Stone's father, may possibly have been an exceptionally enlightened district at the time referred to by Dr. Ackerley in his letter in your issue of April 5th, and thus may have corrected the prevalent London vernacular. I knew Dr. Stone well, however; but among his many tales and witticisms I never heard this rendering of the familiar phrase in question.)

From my student days to the time when I ceased to see out-patients in the East of London I frequently heard this magniloquent phrase, which always indicated "spit" as a *fact*, but "lung disease,' or "consumption," as the patient's *diagnosis.*

I am, Sir, yours faithfully,

Ventnor, April 5th, 1913. H. BRYAN DONKIN.

To the Editor of THE LANCET.

SIR,—The many communications that have appeared in THE LANCET in response to the question mooted in your annotation of March 15th have not removed that question from the region of conjecture. I submit that, as far as affecting horned cattle at any rate, the following heading to one of the sections in an old book is unequivocal. "Of the Inflammation of the Lungs, commonly called the rising of the Lights." The book is entitled, "A Treatise on the Disorders incident to Horned Cattle," its author's name is Thomas Rowlands, and it was printed at Bangor by John Broster in 1812. "Rising in the Body," mentioned in the annotation as given in Bailey's Dictionary, 1737, as the name of a distemper in cattle, is not among Rowlands's disorders.

I am, Sir, yours faithfully,

April 8th, 1913. W. R.

HEALTH OF ST. LUCIA.

ACCORDING to the report on the Blue-book of St. Lucia for the year 1911-12, just presented to Parliament, the estimated population of the colony on March 31st, 1912, was 49,205—22,521 males and 26,684 females. The birth-rate for the year ended on the same date was 35·5 per 1000 and the death rate 20·2 per 1000, still births being excluded in each case. There were 251 marriages during the year. All the medical officers report the health of the colony during the year to have been generally satisfactory, with the exception that in the Castries, Soufrière, and Vieux Fort districts there were outbreaks among children of measles and whooping-cough, whilst a sharp outbreak of *influenza occurred in Castries during* the month of February. Sanitary matters received strict attention during the year, and the work continues to be well carried out. The heavy rains, it was found, washed out the "millions" fish that had been distributed in certain localities to keep down the number of mosquitoes. The places were at once re-stocked, and the fish soon regained their former numbers. The average rainfall at 20 stations in the year 1911 was 114·01 inches. The mean monthly temperature in the shade was 78·4°F; the maxium shade temperature was 92° on Sept. 16th and the minimum 60° on Feb. 19th.

The only general hospital in the colony is the Victoria Hospital, within half a mile of Castries, a large stone building with outhouses, &c., capable of accommodating 80 patients. The daily average during 1911-12 was 65, and the cost worked out at £26 per head. Considerable outlay has been incurred latterly in connexion with this institution in an attempt to improve and uplift the tone and condition generally, which is meeting with fair success. In the town of Soufrière and at the villages of Vieux Fort and Dennery, where there are resident medical officers, small buildings are provided and fitted to serve the purposes of casualty hospitals, and as such are very useful. There are seldom more than two or three cases under treatment at a time at these places, and often they are empty. *Situated on a breezy spot near the sea beach within a mile of the town of Soufrière is the general poor asylum,* which takes in and makes good provision for the human wreckage of the colony, the majority of which drift there only in the last stage preceding dissolution. This provision for paupers of the island is supplemented by an outdoor relief system under the supervision of the Police Department. Lower down on the shore itself is the Yaws Asylum, with a daily average of about 46·42; and here also, in addition to yaws patients, two or three lepers are housed, for whom separate accommodation has not yet been provided. There are visiting stations at various *points where medical officers attend regularly on fixed days,* and are available to those who require their services. At Castries the medical officer in charge of the Victoria Hospital dealt with a very numerous out-patient *clientèle* from the town at the hospital dispensary, but this has now been changed and a separate dispensary established in the town, which is a preferable arrangement.

THE REMOVAL OF TATTOO MARKS.

R. B. (M.D.) writes.—I have a patient, a girl, who some time ago was tattooed by her mother on the face. The friends are now anxious to get the marks erased. Can you, or your readers, inform me how this can be done, and oblige?

*** There are several methods by which tattoo marks may be removed, and the choice of the method to be employed depends on the character of the marks. If they are small and scattered the electric needle is best suited for removing them; if they are larger a skin punch will often prove useful, while if they are very extensive some form of skin-grafting will be the most suitable method to employ. It is obvious that much skill is required in the use of these methods to prevent the replacement of one form of disfigurement by another. When the operation is carefully done the results are very good. Caustics are, on the whole, unsuitable, and the scars produced are not sightly.—ED. L.

A TUBERCULOSIS CIRCULAR.

AN instructive circular on tuberculosis prevention comes to us in the shape of *Bulletin*, No. 9, Vol. II, of the Tuberculosis League of Pittsburgh, U.S.A. The circular gives reasons for stating that in order to prevent tuberculosis we must take care of our children from the cradle through childhood, details the statistics of tuberculosis in childhood, and of [illegible] to the questions, [illegible] handled? What [illegible] and institutions, in schools, in Sunday schools, in playgrounds, and in hospitals? and How can these weaknesses be reached in each of the foregoing environments? It urges the formation of a series of hospital schools in which the sick tuberculous children from the public schools can be helped to regain health while continuing their education, and of a series of open-air schools for anæmic and backward children. It also details the things accomplished by the league as follows: the establishment of an open-air school, a hospital school, a babies' dispensary, and an orphanage open air school. A plan for the systematic education of school children on tuberculosis which was devised by the league received the second prize at the International Congress, and has been widely copied.

STRAITS SETTLEMENTS' HEALTH REPORT.

THE annual report on the Straits Settlements for the year 1911 (not [illegible] the population [illegible] The death- [illegible] compared with 41·88 in 1910 and 37·40 in 1909. The birth-rate in 1911 was 25·38 *per* 1000, compared with 27·55 in 1910. There were 393 deaths from small-pox, 343 from cholera, and 32 from plague. The deaths from beri-beri were 2056, as compared with 1737 in the previous year. The use of cured rice in the different institutions of the colony has lessened the death-rate from this disease.

Phthisis increased in a markedly unhealthy year, there being 2907 deaths returned *from this disease, compared with* 2571 *for* 1910, 2659 in 1909, and 2938 in 1908. It must be remembered (the report points out) that with greater facilities for travelling in *the Straits more* decrepits find their way into the big towns to increase the death-rate, and the population is shown to have increased 139,702 in the past ten years. Improvement in the death rate from this disease is hoped to be shown in a few years when time is given for the sanitary conditions *of the bigger towns to improve by the gradual construction of* back lanes, improved drainage, more cubic space and less overcrowding, more air and sunlight, &c.—matters now being taken in hand by the municipalities.

Dysentery was the cause of 2035 deaths, as against 1329 in 1910 and 1211 in 1909. A large addition to the water-supply of Singapore has but lately been completed; improvement of the water supply of other districts is under consideration, and it is trusted that progress on these lines may tend to lessen the incidence of the disease. There was widespread increase of malaria throughout all the Settlements—an increase which has been steady and progressive for several years. The death-rate from this disease also shows corresponding increase, a conspicuous feature being the number of cases of a malignant type. The deaths from malaria in all Settlements (excluding Labuan) were 5769 for the year, compared with 3245 in 1910 and 2589 in 1909. A crusade against this disease is being undertaken, but some years must elapse before any very tangible results are likely to be seen. An Estate Labourers' Protection of Health Ordinance has been passed which should lead, when in full work, to some reduction in the death-rate, more especially from malaria and dysentery, for it is undoubted that many broken-down coolies from estates proceed to the nearest town, where they not only increase the death-rate but are also a source of danger to those around them. The accommodation in all hospitals was taxed to the utmost throughout most of the year. The total number of admissions was 44,026, as compared with 32,979 in 1910 and 27,543 in 1909. The rate of mortality in 1911 was 13·04 per cent. (as against 12·69 per cent. in 1910) of the total cases treated. The number of inmates in the leper asylums increased from 440 to 471, and there were 173 deaths.

The mean temperature of the air in Singapore was 81·3°F, in Penang 81·7°, in Province Wellesley 81·4°, in Malacca 80·0°, and in Labuan 81·6°. The rainfall was 92·72 inches in Singapore, 99·82 in Labuan, 85·70 in Penang, 68·65 in Wellesley Province, 67·44 in Malacca, and 82·2 in Dindings. The prevailing direction of the wind changes with the N.E. and S.W. monsoons, the former blowing from November to April, and the latter from May to October.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

Discussion:

On Alimentary Toxæmia: its Sources, Consequences, and Treatment. (Second Meeting.)

The discussion will be re-opened by Mr J. B. Lawford and continued by Prof. W. E. Dixon, F.R.S., Dr. J. C. G. Ledingham, Dr. James Galloway, Dr. A. Mantle, Dr. A. F. Hertz, Mr. J. G. Turner, Mr. Frank Coleman, Mr. S. H. Browning.

The Third Meeting will be held on Monday, April 21st, at 5 P.M., when the discussion will be re-opened by Mr. Lockhart Mummery.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries: H. H. Dale, W. Langdon Brown): at 4.30 P.M.

Discussion:

On the Use of Salvarsan and Neosalvarsan in Diseases other than Syphilis (to be opened by Dr. Byrom Bramwell: Use in Pernicious Anæmia).

Dr. Parkes Weber, Dr. William Hunter, Dr. T. J. Horder, and Mr. J. E. R. McDonagh will take part.

The Hon. Secretaries will be glad to hear from Fellows of the Society or Members of the Section who can contribute to the discussion.

GENERAL MEETING OF FELLOWS at 5 P.M.

Election of Candidates for Fellowship.

THURSDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretary—Chas. W. Buckley): at 5.30 P.M.

Papers:

Dr. Edgecombe: The Significance, Treatment, and Prognosis of High Blood Pressure.

Dr. A. Mantle: The Undesirability in Confirmed Cases of High Blood Pressure of actively applying Therapeutic Means to Reduce it.

SECTION OF DERMATOLOGY (Hon. Secretaries—Wilfrid Fox, J. M. H. MacLeod): at 5 P.M.

Cases:

Dr. Whitfield: An Unusual Case of Papulo-necrotic Tuberculide. And other Cases.

SPECIAL EVENING MEETING: at 8.30 P.M.

Subject:

Malignant and Doubtfully Malignant Tumours of the Skin (with drawings, lantern slides, and microscopical sections.)

SECTION OF NEUROLOGY (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8.30 P.M.

Dr. H. Howard Tooth, C.M.G.: Gumma Cerebri—Results of Treatment, Medical and Surgical. Lantern Demonstration illustrating Histological Features.

Dr. F. E. Batten: Cerebral Symptoms in a Bull-dog associated with Lymphocytic Infiltration of Vessels and Membranes of the Brain and Cord.

Dr. James Collier and Dr. S. A. K. Wilson: The Clinical and Pathological Data of a Case of Dermato-myositis with Intense Muscular Atrophy in the Cervical Region and Disease of the Thyroid Gland.

FRIDAY.

SECTION OF OTOLOGY (Hon. Secretaries—H. J. Davis, G. J. Jenkins): at 5 P.M.

Discussion:

On Functional and Simulated Affection of the Auditory Apparatus (to be opened by Mr. T. Mark Hovell).

SECTION OF ANÆSTHETICS (Hon. Secretaries—H. J. Scharlieb, C.M.G., H. E. G. Boyle): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1913–1914.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—Cecil R. C. Lyster, G. Allpress Simmons): at 8.30 P.M.

Consideration of the Use of X Rays in the Diagnosis of Gastric Ulcer.

Papers:

Dr. A. C. Jordan: Gastric Ulcer.

Dr. A. E. Barclay: The Etiology of Gastric Ulcer.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical Cases and Pathological Specimens will be exhibited by Dr. F. P. Weber, Mr. E. M. Corner, Mr. C. V. Anderson, Dr. J. L. Bunch, Dr. E. H. Shaw, Dr. Jewesbury, Mr. A. E. Barker, and others.

CHARITY ORGANISATION SOCIETY, *Denison House, Vauxhall Bridge-road, S.W.*

MONDAY.—4.30 P.M., Special Meeting of the Council. Mr. H. D Scott and Mr. W. Buckley: The Best Means of Increasing the Supply of Pure Milk.—Dr. R. Dudfield: The Supply of Suitable Milk for Infants.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., *Demonstration of Pathological Specimens. Cases sent for Consultation.* Demonstration of Clinical Cases by Dr. Dockrell, Dr. Bunch, Dr. Sibley, Dr. Galbraith, and Dr Griffith. 5.15 P.M., *Discussion on Electrical Procedures in Diseases of the Skin and Mucous Membranes (opened by Dr. W. K. Sibley).*

CHELSEA CLINICAL SOCIETY, Club Rooms of the Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Papers:—Dr. V. B. Orr: The Work of a Tuberculin [illegible] The Use of Tuberculin in Diagnosis [illegible] y a Discussion in which Dr. Barcroft, [illegible] F. N. Griffiths, Dr. C. McClure, and others will take part.

CHILD STUDY SOCIETY, LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—7.30 P.M., Prof. J. A. Green: The Backward Child in the Ordinary School.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Hypertrophy. (*Museum Demonstration.*)

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating Congenital and Acquired Deformities of the Foot. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

TUESDAY.—4 P.M., Dr. E. B. Smith: Clinique (Medical). 5.15 P.M. Lecture:—Mr. R. Lake: [illegible]

WEDNESDAY.—4 P.M., Mr. R. F [illegible] 5.15 P.M. Lecture:—Mr. E. Clarke [illegible] Health (illustrated [illegible] Fundus Oculi, contrasted [illegible] by lantern slides).

THURSDAY.—4 P.M., Mr. J. Cunning: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. E. M. Corner: Alimentary Intoxication.

FRIDAY.—4 P.M., Mr. J. Cunningham: Clinique (*Eye*).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 [illegible] Women. 2 P.M., Medical and Surgical Clinics. [illegible] 2.30 P.M., Diseases of the Eye

TUESDAY.—10 [illegible] 2 P.M., [illegible] and Surg [illegible] es of the Throat, Nose, and Ear. 2.30 [illegible] s of

WEDNESDAY.—10 A.M., Diseases of Children. [illegible] Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operati [illegible] Diseases of Women [illegible] X Rays. Opera

THURSDAY.—2 P.M., [illegible] the Eye. [illegible] tions. Orthopæ [illegible] 2 P.M., Medical and

FRIDAY.—10 A.M., Gynæcologi [illegible] the Throat, Surgical Clinics. X Rays. [illegible] Nose, and Ear. 2.30 P.M., [illegible] ions of

SATURDAY.—10 A.M., [illegible] ye. 2 P.M., Medical Throat, Nose, and [illegible] and Surgical Clinic [illegible]

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. [illegible]

Lecture:—Mr. Wm. Turner: Psoas Abscess.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical, Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Radiography.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.

Course of Lecture-Demonstrations on Diseases of the Chest, with Special Reference to Tuberculosis (including a Tuberculin Course):—

MONDAY.—4.30 P.M., Mr. A. Evans.
FRIDAY.—4.30 P.M., Dr. Phear.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Dr. M. Dockrell: Syphilis and Tuberculosis as Modifying Factors in the Diagnosis and Treatment of Eruptions of the Skin.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. W. Bateson: The Heredity of Sex and some Cognate Problems. (Lecture I.)
FRIDAY.—9 P.M., Dr. T. M. Lowry: Applications of Polarised Light (with experiments).

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. A. Renshaw: The Application and Interpretation of the Wassermann Reaction (Post-Graduate Clinic.)

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MON[illegible] the Presenta-[illegible] 11 A.M., [illegible]
TU[illegible] in Gynæcological Diagnosis.
WEDNESDAY.—10 A.M., Obstetrical Lecture: Mechanical Obstacles to Delivery. 11 A.M., Examination of Patients and Minor Operations.
THURSDAY.—10 A.M., Major Operations
FRIDAY.—10 A.M., Gynæcological Lecture: Pelvic Infection. 11 A.M., Examination of Patients and Minor Operations. 4 P.M., Class in Gynæcological Diagnosis.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Hunterian Lectures

ON THE

PRINCIPLES AND TECHNIQUE OF THE OPERATIVE TREATMENT OF MALIGNANT DISEASE OF THE MOUTH AND PHARYNX.

Delivered before the Royal College of Surgeons of England on March 3rd and 5th, 1913,

By WILFRED TROTTER, M.S. Lond., F.R.C.S. Eng.,
ASSISTANT SURGEON, UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

Delivered on March 3rd.

Mr. President and Gentlemen,—The respects in which the surgery of cancer of the mouth and pharynx falls below the standard that has been reached in many other departments of the art may be classified in three groups. First and most important is the uncertainty of cure; secondly, the danger of the operation and the distresses of the convalescence; and thirdly, the mutilation and disability which may be left by an operation otherwise perfectly successful.

The Uncertainty of Cure.

There can be no doubt that this is the great stumbling-block of surgeon and patient alike. It prevents the latter seeking advice in the earliest stages of his malady because he usually suspects its nature and is probably possessed of the deeply rooted conviction that cancer is incurable, while the former is discouraged from the hopeful and enterprising attitude which alone can lead to progress. He is aware that in any but the earliest cases he may submit his patient to a dangerous operation and a distressing convalescence, only to leave him still a victim to the disease the course of which will, perhaps, not even have been mitigated. This consideration applies, no doubt, to all operations for malignant disease, but is of particular force in regard to malignant disease of the mouth and pharynx. Here, when recurrence after operation takes place, it usually does so within a few months, so that the patient has not even secured from the treatment a moderate interval of comfort and good health.

This liability to early recurrence has, however, one less gloomy aspect, and that is, that should the patient remain well for a relatively short time he may be assured that the chance that permanent cure has been effected is very great. Many authorities seem to be of opinion that a year's freedom from recurrence is good evidence of cure in the case of squamous epithelioma. I have myself seen only one case in which a true recurrence occurred after a longer interval, and would venture the opinion that if at the end of 12 months from the operation the most careful examination fails to show any suspicion of disease, a very favourable prognosis may be given. Such a decision must, however, be founded on very careful examination, and needs a certain amount of experience to give it much value. For the purpose of considering the results of treatment in general it is, I think, desirable to double the period of probation, and not to regard cases as cured with any certainty until two years have elapsed. In these remarks I am, of course, leaving out of account cases of a second outbreak of the disease, such as will occur, for example, in a distinct part of a leucoplakic tongue many years after a growth has been removed.

An early superficial carcinoma on the free part of the tongue, if treated with due regard to modern principles, should be, and is, curable in practically all cases. The principles, through the application of which such results can be obtained, we owe to the late Sir Henry Butlin.* His formulation of upon a systematic gla work in the advancem lculably enlarged the resources of surgery, and have furnished other workers in the field of his enthusiastic labours with a rich endowment of hope.

When, however, we turn to the more advanced cases and to growths in less easily accessible regions, we find the extent to which we can expect cure in any given case is greatly reduced. It is just in these cases that a reason prospect of success would be of the greatest value. very far from suggesting that there should be any relax in our efforts to secure early diagnosis, but I am incline think that until we can attain at least fairly good resul the moderately advanced cases—that is to say, the ave cases—it will be difficult to get the public to appreciate great advantages of early diagnosis. The general convic of the incurability of cancer is founded on the result operation in the average fairly advanced case, and until conviction is shaken I fear the public will remain relati indifferent and pessimistic as to the advantages of e treatment. Every surgeon of any experience is aware as regards its accessibility to treatment early cancer totally different disease from even moderately advar cancer, but I am very doubtful as to whether we shall be able to enforce this fact by direct statement so lon the treatment of advanced cases furnishes the public so many terrible object lessons in the apparent intractab of the disease.

Varieties of Malignant Disease met with in th Mouth and Pharynx.

In inquiring into the difficulties of eradicating maligr disease of the mouth and pharynx, the first step is analyse as far as possible the varieties in which disease occurs. The clinical and pathological study of part of the subject does not seem to have been follo out as fully as it might have been, and I believe it is generally appreciated how regularly the disease tends follow certain types and to infest certain regions, how much information for the guidance of treatment prognosis can be got from a familiarity with these cha teristics.

ANATOMICAL VARIETIES.

The Mouth.

The distribution of malignant disease within the mouth so familiar that no detailed description is necessary. I cardinal types are recognisable:—

(*a*) Growths of the oral part of the tongue—that is, of part of the tongue which lies in front of the circumval papillæ and is clothed on its dorsum and margins v papillary mucous membrane. Usually the tumour begin the lateral margin, frequently on the dorsum, and someti on the under surface.

(*b*) Growths of the floor of the mouth. These begin ei on the sublingual fold between the tongue and the m teeth or on the frænum of the tongue. A distinct differe in the malignancy of the two forms is frequently to observed.

(*c*) Growths of the gum starting in the mucous membr around the teeth. This form may cause difficulties diagnosis. The bone is involved early. In the lower jav may merely be exposed by the growth; in the upper jaw bone being much less dense is apt to undergo ra destruction, with perforation of the antrum. Very often these cases the direct evidence of the presence of malign disease is slight and ambiguous.

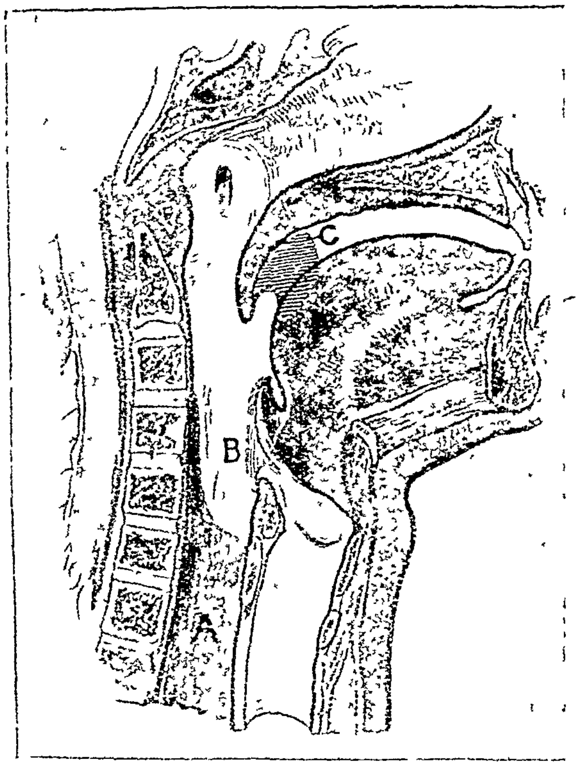
(*d*) Growths of the cheek are the least common. Th usually start somewhat outside the angle of the mouth closure of the jaws and the suppuration in the cheek n cause the diagnosis of an inflammatory lesion to be made

The Pharynx.

It is in regard to this group that the recognition of different anatomical types is most important Ea diagnosis and satisfactory treatment may depend entir upon the identification of the exact form of the disease, a it frequently happens that such identification is by no mea easy unless it is founded on considerable experience. T growths of the pharynx seem to have been but litt described and classified from the point of view of the starting-points. Post-mortem evidence is, of cours valueless, since death does not usually occur until th growth has spread widely. Clinical evidence obtained by examination by the laryngoscope or by the direct meth has frequently proved in my experience to be most m leading. The only means which can give exact informati of these tumours in their early stag is the direct observation of these tumours in their early stag at operations undertaken for their removal. No ve valuable statements can be made, therefore, until our experience derived from this source is much larger. I shall, therefore, give merely a provisional classification based on my own operative experience. I may add, with regard to methods of examination, that I attach far more importance to palpation with the finger than to any other method. As far down as the upper opening of the larynx it is a source of information superior to any other. External examination of the neck, as we shall see later, is sometimes of great value in the diagnosis of the primary tumour, and occasionally is all that is necessary. Finally, I would remind you of the fact, familiar to all, that almost invariably at operation the growth is found to be more extensive than was expected, and sometimes very much more extensive.

Tumours of the pharynx lend themselves readily to classification into fairly definite groups. The various groups which can be distinguished are of great practical importance, since for each of them a standard operation can be devised which gives adequate means of dealing with any operable tumour of the given group. The differentiation is not, however, merely anatomical, but corresponds also fairly accurately with certain peculiarities of age and sex incidence.

FIG. 1.



Diagrammatic section of pharynx to show situation of three of the principal regions in which tumours mainly occur. A, Hypopharyngeal group. B, Epilaryngeal group. C, Oropharyngeal group.

Seeing that adequate exposure of a given tumour is an essential preliminary to satisfactory removal of it, it is obviously of great importance for the surgeon to recognise the class to which the tumour belongs and thus to be able to choose the proper method of attacking it, for an unsuitable method of approach may render impossible the satisfactory completion of the highly complex operation which is often desirable.

The anatomical classification which I have found most convenient is as follows: (1) nasopharyngeal tumours; (2) oropharyngeal tumours; (3) epilaryngeal tumours; (4) tumours of the sinus pyriformis; and (5) hypopharyngeal tumours. (Fig. 1.) Each of these groups must be dealt with by a special operation, whereby any member of the group can be exposed and if operable removed.

1. *Tumours of the nasopharynx.*—This group is peculiar in two important particulars: first, in that the squamous epithelioma is almost entirely absent from it; and secondly, because symptoms are often very inconspicuous in the early stages, so that it is almost impossible for a diagnosis to be made at a period when successful treatment is possible. In my experience almost all true malignant tumours here are endotheliomata of a peculiar and characteristic type. A sarcoma is occasionally found. All these occur on the roof and lateral wall, especially the latter.

The symptoms may be divided into three groups.

(*a*) *Pharyngeal.* Hæmorrhage, obstruction of the nose. Both these are much less common than is sometimes thought, and this is perhaps a reason why a diagnosis is often not made.

(*b*) *Symptoms due to direct extension of growth.* Into the lateral wall, causing unilateral fixation of soft palate, deafness from pressure on Eustachian tube, trigeminal neuralgia through involvement of inferior maxillary nerve and sometimes superior maxillary nerve, closure of jaws through extension to internal pterygoid muscle. Into the skull through the basal foramina, causing symptoms of cerebral tumour. This latter mode of extension is relatively late; the former relatively early.

(*c*) *Enlargement of glands.* This occurs early, and on account of the relative absence of nasopharyngeal symptoms is apt to cause difficulty. The glands are characteristic clinically. They are firm but accompanied by much periadenitis, so that they are frequently mistaken for glands of inflammatory origin. One of my patients had been treated with tuberculin for six months before I saw him. As a matter of fact, the condition clinically does closely resemble the fibrotic variety of tuberculous glands and to some extent gummatous glands.

The endothelioma of the pharynx is a remarkable and interesting tumour, presenting many very characteristic features which have not, however, received much attention on account probably of cases not having been operated on very frequently. I shall not be able to deal with these tumours fully here, but may mention their especial frequency in the young adult and adult male, the liability to show inflammatory signs and to suffer inflammatory complications such as recurrent suppuration, and their extreme intractability to operative treatment in any but the very earliest stages. The area in which they occur does not exactly correspond with the anatomical classification I have given, as in addition to the lateral wall of the nasopharynx and to some extent the roof, they originate in the tonsil not very uncommonly. It is perhaps worthy of note that the tract of tissue about the inner ends of the two first visceral clefts is that to which this very special class of tumour is practically limited.

I have known of cases in which such a tumour has been found in a tonsil which has been removed by enucleation and in which no recurrence has occurred. The more fully developed cases with which alone I have had to deal have proved quite inveterate. The disease can be checked for a time but not cured. In all these cases, however, the diagnosis might have been made very much earlier had the special features of the disease been more generally known. In regard, therefore, to endothelioma of the nasopharynx and tonsil (pharyngeal endothelioma) we are at present entirely dependent upon very early diagnosis, and until that is generally mastered the surgeon will remain unable to give any good hope of cure.

2. *Tumours of the oropharyngeal region.*—The term oropharyngeal is conveniently used to indicate a group of tumours which all begin within a comparatively small area and can all be exposed for removal by a single standard operation. The region centres about the tonsil and includes the anterior faucial pillar and the pharyngeal part of the tongue—that is, the part behind the circumvallate papillæ. Some further reference to the various growths occurring here is desirable.

(*a*) True tonsillar tumours Of these epithelioma is the most common, but I have also met with endothelioma and mixed-cell sarcoma Lymphosarcoma I have never seen at a stage in which the tumour offered the least prospect of curability by operation. Epithelioma, the most important tumour, tends to spread into the tongue to some extent, but chiefly downwards along the groove between the tongue and lateral pharyngeal wall into the pyriform sinus. This marked tendency to longitudinal spread renders free longitudinal exposure an essential necessity in the operative technique.

(*b*) Faucial pillar growths. These are always epitheliomata and are not at all rare. They begin on the front of the anterior pillar and soon involve the tongue and tonsil, tending to spread in exactly the same way as true tonsillar growths.

(c) Lingual growths. Two forms of epithelioma beginning in the tongue are included in the group. First, the common type which begins just at the lingual attachment of the pillar in the neighbourhood of the remains of the foliate papilla. The importance of this interesting vestige was first shown by Butlin. He called attention to the frequency with which it becomes irritated by the last molar tooth and gives rise to the erroneous diagnosis of epithelioma. It must be remembered also—and this increases the difficulty of diagnosis—that this very spot is, in fact, a common starting point for epithelioma.

The second form of lingual carcinoma which comes into this group is that most formidable variety which begins in the part behind the circumvallate papillæ, generally near the middle line. It owes its seriousness to the remarkable tendency it has to grow into the substance of the tongue without in the early stages ulceration or projection at the surface. Thus it happens that the disease runs for a considerable time a practically symptomless course. Some discomfort in swallowing, some slight limitation in protrusion of the tongue, and some slight induration of its substance in the hindmost part are for long the only signs. The most difficult and dangerous of all the operations on the tongue is necessary for the removal of the tumour, and the results in my experience are correspondingly bad. Possibly good results might be got if the clinical picture of the disease were more widely known and operation fairly early in the case rendered possible. It must always, however, remain one of the graver forms, since the absence or ambiguity of the early symptoms is such as often not even to arouse the patient's attention.

3. *Tumours of the epilaryngeal region.*—The remaining types we have to deal with are all epitheliomata, and this fact simplifies to some extent the full discussion of them which is necessary.

The term "extrinsic cancer of the larynx" is one which has long been current as a name for tumours involving the pharynx in the neighbourhood of the larynx. It served a useful purpose in marking a distinction from the true intralaryngeal tumours or "intrinsic cancers of the larynx," but it helped to encourage the belief that "extrinsic" tumours, being essentially laryngeal, could be dealt with only by extirpating the larynx. Without prejudice to the question of the necessity or otherwise for laryngectomy, it would be more in accordance with fact to describe all such tumours as essentially pharyngeal in origin, and to reserve the term laryngeal cancer for the growths beginning in and about the vocal cord—that is, the "intrinsic" cancers.

Of such pharyngeal tumours as arise in the neighbourhood of the larynx, those which begin in or near the margin of the upper opening form a group so distinct in their characters and so uniformly accessible by a single operation, that I venture to distinguish them under a special name as the epilaryngeal tumours of the pharynx. These growths may originate upon the aryteno-epiglottic fold or upon the epiglottis itself. The latter situation is, in my experience, decidedly the commoner. Neither form has any great tendency to invade the essential parts of the larynx. Perhaps, however, it would be better to say that at the time of operation it is usually found that a considerable margin of healthy tissue is present between the growth and the vocal cords; sometimes, indeed, the whole circumference of the upper opening is affected before the vocal cords are reached. The relative freedom of the body of the larynx in these cases is probably due less to any essential benignity of the growth than to the earliness of the period at which it produces symptoms. There is, perhaps, no single feature which affects the treatment of malignant disease of the mouth or pharynx more favourably than the growth being in a situation which leads to early and severe symptoms.

The symptoms of the epilaryngeal group are an alteration in the quality of the voice, giving it a peculiar "throaty" character, hoarseness, difficulty in swallowing, and difficulty in breathing.

The general behaviour of these growths as regards treatment is favourable. They can be dealt with at least frequently without laryngectomy, and permanent cure can undoubtedly be obtained in moderately early cases. As far as my small experience goes I should regard this group as the most hopeful of all malignant pharyngeal tumours, and I have no doubt that the treatment of them can be firmly established as a standard measure with results satisfactory as to safety, as to the absence of serious mutilation, and as to the attainment of cure.

4. *Growths of the pyriform sinus.*—In the immediate neighbourhood of the larynx there occurs, however, another growth which presents a remarkable contrast with the epilaryngeal group as to symptoms, mode of extension, and curability. This is the tumour starting in the pyriform sinus, a tumour the frequency and importance of which have, I think, been greatly under-estimated.

I must remind you that the pyriform sinus is the deep recess which lies under cover of the ala of the thyroid cartilage between this and the upper opening of the larynx. Its external wall is the ala, its inner wall from below up the cricoid cartilage, the lateral part of the cricothyroid membrane and the structures of the aryteno-epiglottic fold. It is lined by a lax mucous membrane forming a diverticulum of the pharynx large enough in the adult male to admit the last joint of the thumb. Its cavity is quite inaccessible to laryngoscopic examination, which reveals only its mouth and would leave quite unsuspected the considerable recess that lies in front of this. It is usually just accessible to digital exploration, and can also be examined with the bronchoscope.

Growths originating here frequently run an absolutely latent course until they are far advanced. Often the first serious symptom is the appearance of a mass of glands in the neck, which on account of the absence of pharyngeal troubles the patient may ignore until they are quite inoperable. In the frequent cases of obviously malignant glands in the neck without ostensible primary tumour the sinus pyriformis should always be most carefully examined.

FIG. 2.

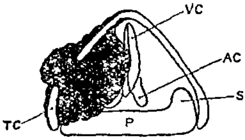


Diagram of section of larynx to show distribution of epithelioma of sinus pyriformis. VC, Vocal cord. AC, Arytenoid cartilage. SP, Sinus pyriformis. P, Pharynx. TC, Thyroid cartilage. The growth is in a moderately advanced condition and at about the stage when surgical advice is

black.

These tumours spread in an extremely characteristic way. Starting in close contact with the thyroid cartilage they early involve the perichondrium of this and extend diffusely beneath it, leading to a subperichondral growth of epithelioma, which spreads insidiously until it may have affected widely the ala of the opposite side. Meanwhile the cartilage itself is attacked and comparatively soon perforated near the spot where the growth starts. A swelling then forms on the outer aspect of the ala, and tends also to be surrounded by a diffuse subperichondral thickening. Such a swelling is sometimes mistaken for a gland, but can usually be distinguished from such if the surgeon is familiar with these cases. Internally the growth tends to invade the lateral wall of the larynx, where it causes an œdema visible in the laryngoscope and later on fixation of the cord. It is quite rare for the growth to break through into the larynx and ulcerate there, but it tends to spread round the cricoid in close relation to the perichondrium. (Fig. 2.)

and the lateral wall of the larynx below it; (2) a persistent pool of muco-pus between the arytenoid cartilage and the lateral wall of the pharynx, while the opposite side is quite free; (3) some thickening on the outer aspect of the ala of the thyroid and firmly fixed to it. No ulceration is visible by laryngoscopic examination.

Later the tumour emerges from the recesses of the sinus and begins to attack the lumen of the pharynx. Here it tends to spread circularly and downwards towards the œsophagus. The extension round the pharynx, added to that round the larynx, gives the growth a figure-of-eight shape, and makes it the most formidable of all the pharyngeal epitheliomata.

The difficulty of diagnosis in anything like an early stage is scarcely credible. I have never seen a case in which at the time of operation the thyroid cartilage itself was not extensively invaded and perforated. In my experience, therefore, a total laryngectomy has always been obligatory. Fortunately, however, I believe this is the only tumour of the pharynx for which that terrible operation is invariably necessary, but it would seem that it must remain such unless our methods of diagnosis can be greatly improved, or until the desirability of exploratory operations on the pharynx in the presence of certain symptoms is generally accepted and enforced.

The chief cause of difficulty in the diagnosis is the laryngoscopic picture. This shows a smooth rounded swelling of the lateral wall of the larynx above the vocal cord, and usually no ulceration at all. These appearances lead to the diagnosis of an inflammatory lesion, usually gumma. The signs by which a correct opinion can be formed are the pool of muco-pus which fills the mouth of the sinus and betrays the presence of ulceration within, and the evidences of invasion of the ala of the thyroid. Sometimes a correct diagnosis can be made by external palpation of the larynx alone.

5. *Tumours of the hypopharyngeal region.*—A very well-marked group of tumours affects the lowermost parts of the pharynx below the opening of the larynx, and is thus conveniently described as hypopharyngeal. Certain tumours which occur somewhat beyond the limits of the hypopharynx of descriptive anatomy are so obviously similar that it is desirable to include them in the same group, which thus comes to comprise growths beginning in any part of the circumference of the pharynx below the upper opening of the larynx and on the posterior wall of the pharynx as high as the level of the epiglottis. Such tumours, occurring as they do for the most part on the narrowest part of the pharynx, usually produce difficulties in swallowing comparatively soon. Diagnosis, therefore, is possible at a fairly early stage. The late period at which most of my cases have been submitted to operation has been due chiefly to the supposed inoperability of these tumours rather than to diagnostic difficulties. It is sometimes, however, difficult to distinguish clinically between a hypopharyngeal tumour and one of the pyriform sinus. This difficulty is serious when it occurs, for the type of operation undertaken in the two cases would be widely different. Some of these tumours have a tendency to invade the œsophagus diffusely, thus becoming wholly inoperable. When the œsophagoscope tube cannot be passed beyond the growth it may be impossible to detect this extension and an operation necessarily fruitless be undertaken.

Age and Sex Distribution of the Different Groups.

The facts as to the age and sex incidence of carcinoma of the mouth are well known, and I shall, therefore, not trouble you with the addition of my own small experience. I may, however, make the general statements that the disease is probably about ten times as common in men as in women, that in women it occurs at about the same age as it does in men, and that while women are subject to the forms which begin on the tongue and on the gum they seem to be very free from the form which begins on the floor of the mouth.

Growths of the pharynx present some remarkable peculiarities of age and sex incidence which need more detailed description. The *nasopharyngeal endothelioma* in the 10 cases I have had an opportunity of operating on has been a disease of the adult male, usually the young adult. I have seen a case in a young woman, but this is decidedly rare.

In the *oropharyngeal group* there were 9 cases of epithelioma of the tonsil or immediately adjacent parts. All the patients were males between 40 and 60. In addition, there was one mixed-cell sarcoma in an elderly woman and one endothelioma in a young man. In the *epilaryngeal* group there were 10 cases, all epithelioma and all in males between 40 and 60.

The growths of the *sinus pyriformis* have rarely proved suitable for operation, so that the number in which the diagnosis was exactly determinable by inspection was extremely small. Nevertheless, the clinical picture is so characteristic that one's experience of inoperable cases may, perhaps be taken into account. If this be done there can be no doubt that the disease chiefly attacks males between 40 and 60. I have met with one remarkable exception in the case of a typical epithelioma of the sinus pyriformis in a young woman aged 27. The diagnosis was confirmed in this case at operation.

Of the *hypopharyngeal group*, in 5 cases the diagnosis was confirmed at operation and all were in women, most of whom were between 40 and 50. Taking into account numerous other inoperable cases in which the diagnosis was practically certain, I should be inclined to say the lower age limit is too high, and that cases are met with as young as 30 or even under.

To sum up the age and sex incidence of pharyngeal malignant disease, one may say broadly that if a line be drawn across the pharynx from the posterior wall at the level of the tip of the epiglottis to the anterior wall at the interarytenoid notch, all epitheliomata above the line will be in middle-aged and elderly men, while all below the line will be in young and middle-aged women. (FIG. 1, A.)

PATHOLOGICAL TYPES AND AMENABILITY TO OPERATION.

I have already dealt with the peculiarities of the endotheliomata. My experience of sarcomata is not such as to justify any general conclusions; we have, therefore, now to consider the epitheliomata only.

In the first place, I should like to state with emphasis my conviction that at the present time the only treatment of squamous epithelioma which gives any hope of cure is adequate removal by a carefully planned operation. If the sinister reputation of the disease is to be modified at all it can only be through the study of its earlier clinical and pathological manifestations and by ceaseless attempts to improve the design and technique of operations.

Course of the Primary Growth.

It is a commonplace to all surgeons of experience, though apparently unknown to the general public, that cancer in its early stages and cancer in its later stages behave in relation to treatment as if they were two entirely different diseases. It is equally well known that in moderately advanced and even in "early" cases it is often impossible to say whether a given tumour is likely to be curable or not. Cases of an unpromising appearance sometimes surprise us by their satisfactory results, and more often, unfortunately, cases of the most hopeful aspect prove to be of the most inveterate malignancy. We are not, however, entirely without means of forming some estimate as to the curability or otherwise of a given case. A squamous epithelioma is typically a surface growth. If the evolution of the disease be studied throughout its course it will be found that the primary tumour remains for a considerable time essentially a superficial condition; a large proportion of its bulk actually projects beyond the surface of the normal surrounding parts, while the deep aspect of the growth, although, of course, attached to the underlying tissues, can be felt to be marked off from them by an abrupt change of consistence—that is to say, in ordinary clinical terms the outline of the tumour is extremely well defined. After a variable period of growth a change in the physical signs of the tumour is established, and often somewhat abruptly. The deep extension of the growth seems to pass a critical point and then suddenly to increase. The projecting part of the mass no longer forms a large proportion of its bulk and the deep outline has become obscure. We no longer have to deal with the button-like mass inlaid, as it were, in the surface of the tongue, but with a tumour invading the substance. This change in type of growth usually occurs within a few months of the beginning of the disease, but it is sometimes delayed until a late period, and one then sees a large cauliflower growth, which in spite of its formidable appearance is by no means necessarily unsuitable for operation. Now, clinical experience shows that with this change in the mode of spread—often inconspicuous in the clinical features accompanying it—there is a very great increase in the difficulty of obtaining cure by operation. This observation is in accord with the admirable histological work of

Cheatle upon the spread of cancer of the tongue He has shown that when *once the muscular substance* begins to be *freely invaded there is a* very rapid and diffuse infection of the tongue muscles It is in the quiet period before deep extension begins that epitheliomata can be removed with a practical certainty of cure It is probable, however, that some few growths are of the diffuse type from the very early stages Prognosis, therefore, should be based rather on physical signs than on duration

Gland Involvement and its Varieties

If local inveteracy were the principal difficulty in the cure of cancer, it is obvious that, once the distinction between the two grades of the disease was recognised, the results of cancer of the tongue at any rate would be much better than they actually are As is well known, however, the difficulty lies in the involvement of the lymphatic glands, and there can be no doubt that at the persent time a large number of patients are cured of the primary focus of the disease only to die miserably from gland infection We owe chiefly to Butlin the firml [illegible] primary disease [illegible] has begun, witl [illegible] operation should be as much a part of the treatment as the removal of the primary growth So essential is this principle, and so invariable should be this rule, that I would go so far as to say that it has actually been a hindrance to progress that certain cases do not develop a gland *infection although treatment has been limited to removal of the* primary growth All of us, no doubt, have had patients who have refused to submit to the gland operation, and some few of whom have remained free from recurrence The surgeon is, unfortunately, apt to be unduly impressed by such cases, and to be shaken in his belief in the invariable necessity of the gland dissection, which is at all times a difficult, tedious, and, from the patient's point of view, thankless procedure It is now, however, quite definitely proved that any extensive experience will contain cases in which a gland dissection has revealed distinct foci of cancer, although the primary growth was small and superficial and no glandular enlargement could be recognised clinically The only case in which I have felt justified in relaxing the rule as to the gland operation was in that of a patient aged 91 Here the treatment was definitely regarded as palliative only, and the fact that the patient survived the removal of the primary growth without the least trouble and lived *for several years* entirely free from recurrence is to be regarded as a fortunate accident

The general rule for treatment should, therefore, be based on the knowledge that the primary growth and the possibility of gland infection appear practically together A useful exten*sion of the rule* is the statement that the liability to gland infection bears no relation to the stage of the primary disease—that is to say, that for practical purposes there is no less liability to gland infection before the *period of submucous invasion than there is* after

It is frequently assumed that when the glands are found clinically to be involved to any considerable extent the case is necessarily a hopeless one My experience has not led me to share *this view, and I think that a number of cases* are lost through the undue pessimism of the surgeon discouraging him from submitting such patients to a thorough gland dissection That there are, however, cases of even moderate gland invasion which defy all treatment there can be no *doubt Fortunately,* we are not *quite without clinical* knowledge enabling us to some extent to discriminate between the two types As long as the glands remain hard and well defined, even although they are quite numerous, the possibility of cure is still fair provided a really thorough *dissection is done* If, however, the glands, *though possibly* not numerous or very large, are ill defined, and give the impression rather of inflamed than carcinomatous glands, then the chances are strongly against any operation, however large, proving effective A dozen stony hard, sharply defined *glands are less serious than a single one* of which the outline is obscure and the substance rather yielding In my material I find six cases of really extensive gland involvement which have been cured by operation In two of these the enlarged *glands* were on both sides of the neck and extended *down to the clavicle* Both patients have been free from recurrence for over four years

When the gland enlargement has been moderate and *of* the favourable type I have never seen recurrence after a thorough systematic dissection

Factors Influencing the Occurrence of Submucous Invasion

The onset of diffuse extension to the underlying structures is, as we have seen, an event of crucial importance in the history of the primary growth Capricious as it is, certain factors which influence its early or late occurrence can be made out

(*a*) *Duration of the growth All epitheliomata ultimately* tend to become diffuse, some slowly, some more rapidly. When diffuse extension is well marked and the growth has infiltrated and welded together any considerable body of structures outside the one in which it grew, the case is completely inoperable, and removal, although it seems to be anatomically satisfactory, will be followed immediately by recurrence The recognition of this condition is largely a matter of experience, but in general one may say that a loss of definition in the palpable *outline of a large tumour* is the most important sign

(*b*) Situation of the growth The underlying *structures* may favour the extension of a tumour in various ways, so that the situation has a considerable influence upon submucous invasion The situations in which early invasion is particularly prone to occur are the floor of the mouth on the *sublingual fold, the pharyngeal part of the tongue, and the* sinus pyriformis Consequently these three are the most formidable of all epitheliomata of the mouth and pharynx and can only be dealt with by the most extensive operations

(*c*) Idiosyncrasy of the tumour. The *nodular form of* cancer of the tongue, one of the classical modes of onset of the disease, has a strong tendency to invade the muscular substance from the first, while it has little disposition to project from the surface or to ulcerate It is of far more serious nature, other things being equal, than either the papillomatous or ulcerous form Occasionally tumours of the epiglottis show the same peculiarity and penetrate the tongue early and deeply

The combination of this variety of primary growth with the ill defined inflammatory type of gland is unfortunately common and *almost always defies the most resolute* and extensive operation

THE PLANNING OF THE OPERATION TO SECURE FREEDOM FROM RECURRENCE

I THE PRIMARY GROWTH

Three types of growth present themselves for treatment, the superficial form (early cases), the form in which submucous invasion has begun or may *be suspected (moderately* advanced cases), and the form in which advanced submucous invasion has occurred

(*a*) *Early Cases*

Many of the growths on the tongue and in the epilaryngeal [illegible] are of this type Experience [illegible] the tumour with a margin of tissue [illegible] palpation not less than half an [illegible] will give a practical certainty *of freedom from recurrence* If the growth be certainly of the superficial type there will be no need for the excision to be especially free in any particular direction Under special circumstances the margin may even be less than half an inch, but this should be regarded as undesirable It is *extremely important* that the growth should be centrally placed in the part removed—any excess in one direction is an unnecessary mutilation, while any diminution is a risk In order that such an excision may be carried out deliberately and systematically it is absolutely essential that the surgeon *should obtain* free and untroubled *access to the part* The provision of free access is, in fact, very often the most important part of the operation

(*b*) *Moderately Advanced Cases*

[illegible] *The half inch* [illegible] which it is very [illegible] inch should be looked upon as the desirable limit Moreover, there will usually be certain directions in which the removal should be especially radical For example, in the nodular form of cancer of the tongue or in cases originally superficial which have developed submucous invasion, the muscles of the tongue on the same side must be removed as far as their attachments to the hyoid bone, as has been shown by the histological work of Cheatle. In cases of growths on the sublingual fold the removal posteriorly must be especially free, as it is towards the pharynx that such tumours tend to spread particularly. Growths of the tonsillar region must be removed with a very free inferior margin for similar reasons.

(c) *Advanced Cases.*

Most of them are obviously inoperable. The disease seems to have reached an altogether uncontrollable condition in which it invades the whole region in microscopic outposts. In these circumstances an operation may appear to be anatomically successful in removing the growth with a good margin, but immediate recurrence is the rule and the convalescence, which is distressing enough, merges into the re-established disease. The performance of such operations is a mere virtuosity of surgical technique which exalts the manifestation of skill above its purpose. Nevertheless, there are a few of these desperate cases in which the surgeon of experience will feel compelled to recommend interference.

One can never be absolutely certain that uncontrollably diffuse invasion has occurred, and the submitting of a patient to an unsuccessful operation, distressing as it is, is not so terrible a mistake as allowing to die of cancer unrelieved a patient who might have been cured. In my opinion these very large operations are never justifiable as palliative procedures, and should never be advised unless a distinct hope of permanent cure can be entertained. The actual danger of the operation is, with modern technique, not usually great enough to be an important factor in the decision.

The Anatomical and Pathological Factors in the Planning of Operations.

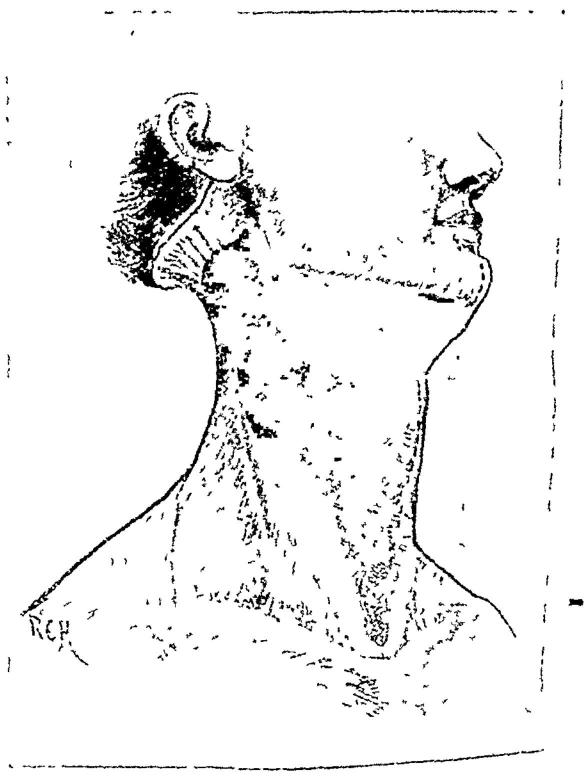
It will be noticed that I have spoken of operations so far strictly in terms of removal of the growth and without any reference to the removal of organs or structures containing the growth. This seems to me an essential principle of the treatment of malignant disease. Most of the operations of surgery were originally designed as anatomical procedures. This was inevitable in view of the difficulties under which the surgeon of those days worked. In the absence of anæsthesia and knowledge of the causes of wound infection it was triumph enough if the surgeon succeeded in removing the tongue, the jaw, the larynx, or so forth, and the possibilities of success were so narrow that any modification of the anatomical procedure to suit the particular disease or an actual example of it was scarcely to be considered. At such a stage of development operative surgery could be perfectly well mastered in the deadhouse. The surgeon there learnt to remove various parts of the body with adequate dexterity, and actual practice was largely a repetition of these chiefly anatomical exercises. The surgeon might amputate a limb, remove the tongue, or excise a joint most acceptably, guided entirely by his experience of operations on the corpse. Frequently, no doubt, the disease was satisfactorily dealt with, but it would be too much to expect that pathological processes should limit themselves to parts of the body which were easy to remove, and in consequence there was always a tendency on the one hand to sacrifice unnecessarily structures which, though not diseased, came within the limits of the operation, and, on the other hand, to spare diseased structures because they lay outside the anatomical region the operation was designed to remove.

To-day the whole basis of operative surgery has changed and the nature of an operation is determined by pathological considerations, anatomical requirements having been reduced by the increase in the resources of the surgeon to a secondary though still important place. There are, however, some vestiges of the influence of the anatomical period still remaining, and it is most important that these should be recognised. We are still apt to go on "excising the upper jaw for malignant disease," undeterred by the fact that in quite a number of cases after the operation has been carried out, in the venerable phrase, "secundum artem," the bulk of the disease, or possibly all of it, has been left behind. The same criticism applies to some extent to excision of the tongue and to laryngectomy for cancer. The gradual replacement of anatomical by pathological indications is going on rapidly, but there is perhaps less conscious recognition of the fundamental change of principle than there might be.

There are very few cases of an anatomical and pathological distribution of disease so exactly corresponding that a precisely designed anatomical operation removes the morbid condition and nothing else. Appendicitis and cholecystitis are instances that readily occur to one, but apart from these and a few such fortunate coincidences surgeons are having more and more to follow pathological requirements in their operations, and to overstep the anatomical boundaries which an older surgery was forced to remain within.

Nowhere is the tendency more marked than in the surgery of the mouth and pharynx, where the pathological requirements of the case must be supreme, so that the attainment of cure and the limiting of mutilation may be subserved at the same time. The formal purely anatomical operation retains, however, a function in providing means of access to the tumour. This function is so important that it should be recognised as a distinct part of the operation.

FIG. 3.



To show extent of gland dissection in early cases. The shaded area is that from which all connective tissue, fat, and glands must be removed.

Since epitheliomata are essentially growths of the mucous membrane the provision of access renders necessary the free exposure of the mucous surface from which the tumour arises. Moreover, access must be allowed which provides for the free removal of the tumour, especially in the direction in which it particularly tends to spread.

We are now in a position to summarise shortly the essentials of an operation which shall give a maximal probability of cure: (1) Free exposure as a formal stage of the operation; (2) exposure of the growth on its mucous aspect; (3) exposure must be capable of indefinite extension along the line of spread of the tumour; (4) removal of the tumour as a definite stage of the operation; and (5) removal to be regulated entirely by the pathological necessities of the case, a precise margin of healthy tissue being included on every aspect, the extent of the margin and its increase in any special direction being determined by the nature of the growth. It will be seen that these requirements are left unsatisfied by many operations for cancer of the tongue carried out through the floor of the mouth, by operations for removal of tonsillar tumours through the same side of the neck, and by many laryngectomies.

II THE GLAND OPERATION

Two types of gland operation are necessary according to whether the glands are much involved or not

(a) Gland Involvement Clinically Slight or Absent

The dissection of the anterior triangle originally designed by Butlin and practised so successfully by him needs extension in two ways to render it an ideal procedure in preventing recurrence First a sufficient number of cases of very early bilateral gland involvement is met with to render the dissection of both sides necessary as an extreme precaution In these early cases it can be carried out without extra risk

Secondly, the operation should aim at removing the deep cervical chain he skull as it is in thi likely to occur This the horizontal extent of the dissection, which must be carried backwards under the sternomastoid to the posterior margin of the muscle Completed in this way, the dissection will be found to comprise about four fifths of the circumference of the neck, from which all lymphoid tissue has been removed In these early cases the horizontal extension of the operation is undoubtedly more important than the vertical, which need not go below the thyroid cartilage (Fig 3)

This posterior extension I regard as absolutely essential, though it makes the operation much more difficult The spinal accessory nerve must first be found and isolated and raised up with the sternomastoid The dense pad of fibrous and fatty tissue between the sternomastoid superficially and the splenius and levator anguli deeply is cut through at the posterior edge of the sternomastoid until the muscles are exposed and then it is turned forwards I have never seen recurrence after this operation when it has been done in suitable cases

(b) Gland Involvement Extensive

In this type of case the bilateral operation cannot usually be done with safety at one sitting Sometimes, when there was no evidence at all of involvement of the opposite side I have omitted the second dissection with success The enlarged glands generally surround the spinal accessory nerve so that there is no question of preserving it The sternomastoid and the jugular vein are also usually either ands so that they the jugular vein tied and divided just above The muscle and vein are raised together with the contents of the triangles It is usually convenient to tie and divide the external carotid at its origin The submaxillary triangle should always be cleared The jugular vein is divided just above the digastric and the sternomastoid at its insertion The operation is much easier than the ordinary bilateral dissection in early cases and takes much less time Moreover the convalescence is shorter as on account of the absence of the sternomastoid there is no cavity for serum to accumulate in The operation looks and sounds much more serious than it is and is usually surprisingly successful in eradicating the disease unless the glands are of the diffuse inflammatory type In addition to it, the dissection of the supraclavicular triangle is sometimes desirable and is not serious

Occasionally in the first six months or so following upon a thorough gland operation a peculiar chronic enlargement of the glands bordering upon the area which has been dissected is to be observed These become moderately enlarged and firm and then remain stationary showing no further progressive change and no fixation They do not lose the ovoid form and do not attain a long diameter greater than about three quarters of an inch The appearance is one decidedly alarming to the inexperienced and is almost inevitably mistaken for a manifestation of recurrence In fact it is scarcely possible for the surgeon not to advise a further operation Such operations I have repeatedly carried out but microscopical examination of the glands removed has invariably failed to show any evidence of malignant disease These experiences lead one to suppose that this kind of enlargement is in compensation as it were for t tissue which has been removed necessary in deciding that in a given case the surgeon has to deal merely with this harmless condition The moderate size of the affected glands and the absence of progressive enlargement are the most important features to be noticed These remarks apply only to cases in which the primary growth was an epithelioma In cases of endothelioma I have never seen gland enlargement which did not prove to be a recurrence

The Limits of Operability in Gland Involvement

In a general way one may say that more mistakes are made in the direction of pronouncing tumours inoperable than in attempting operations which cannot be completed The reason for this is that in advanced gland cases the principal mass is usually under the upper end of the sternomastoid and fixed to it near its insertion This gives the erroneous impression that the growth is fixed to the spine Glands beneath the muscle are also likely to appear ill defined and diffuse when they are in fact not so

When glands not under the muscle are indefinite and accompanied by brawniness of the skin and œdema it is generally quite useless to operate

It is very remarkable how the common and internal carotids and the vagus escape involvement in gland masses until very late Such masses tend to spread backwards and involve the muscles on the floor of the posterior triangle long before they attack the common carotid When the common carotid and vagus are involved it is doubtful whether the operation should be carried out and much would depend on the kind of primary growth and the condition of the patient Removal of these two structures is a serious addition to the danger of disease th operability uselessness of the operation

DENTAL SURGERY TO THE ROYAL COLLEGE
OF SURGEONS OF ENGLAND

THE odontological collection in the Museum of the Royal College of Surgeons of England contains an excellent probably unique, series of specimens illustrating the morbid anatomy of periodontal disease The specimens include examples of the disease in man as well as in the lower animals the value of the collection being enhanced by the fact that all stages of the disease are illustrated The object of this paper is briefly to discuss the more instructive specimens in the collection

1 PERIODONTAL DISEASE AS SEEN IN MAN

Before dealing with the abnormal it will be advantageous to consider the normal In Fig 1 is shown the mandible of a female 22 years of age with an alveolar process which may be regarded as normal The margin of the bone approaches on the buccal aspect to just below the necks of the teeth and is continued across from one tooth to another in a straight line so that a definite triangular space exists between the approximal aspects of the teeth In the incisor region the bone does not follow such a straight line from tooth to tooth but is continued upwards so that the space between the teeth is considerably less than that between the premolars and molars The margin of the bone presents a smooth outline and the surface of the bone is likewise smooth being pierced here and there with nutrient canals The appearance of the bone in skiagrams is shown in Fig 2 Between the front teeth the bone appears to end in a sharp spine while between the back teeth it passes as stated above in a straight line The outer aspect of the bone shows a dense layer the inner portion presenting a cancellous appearance In the maxilla a similar condition obtains

Clinical experience shows that the disease usually commences either in the molar region or around the incisors When the disease commences around the back teeth the initial lesion is a slight destruction of the bone in the centre of the interproximal spaces This early stage is shown in

---

[1] An abstract of a museum demonstration given at the Royal College of Surgeons of England on Nov 6th 1912

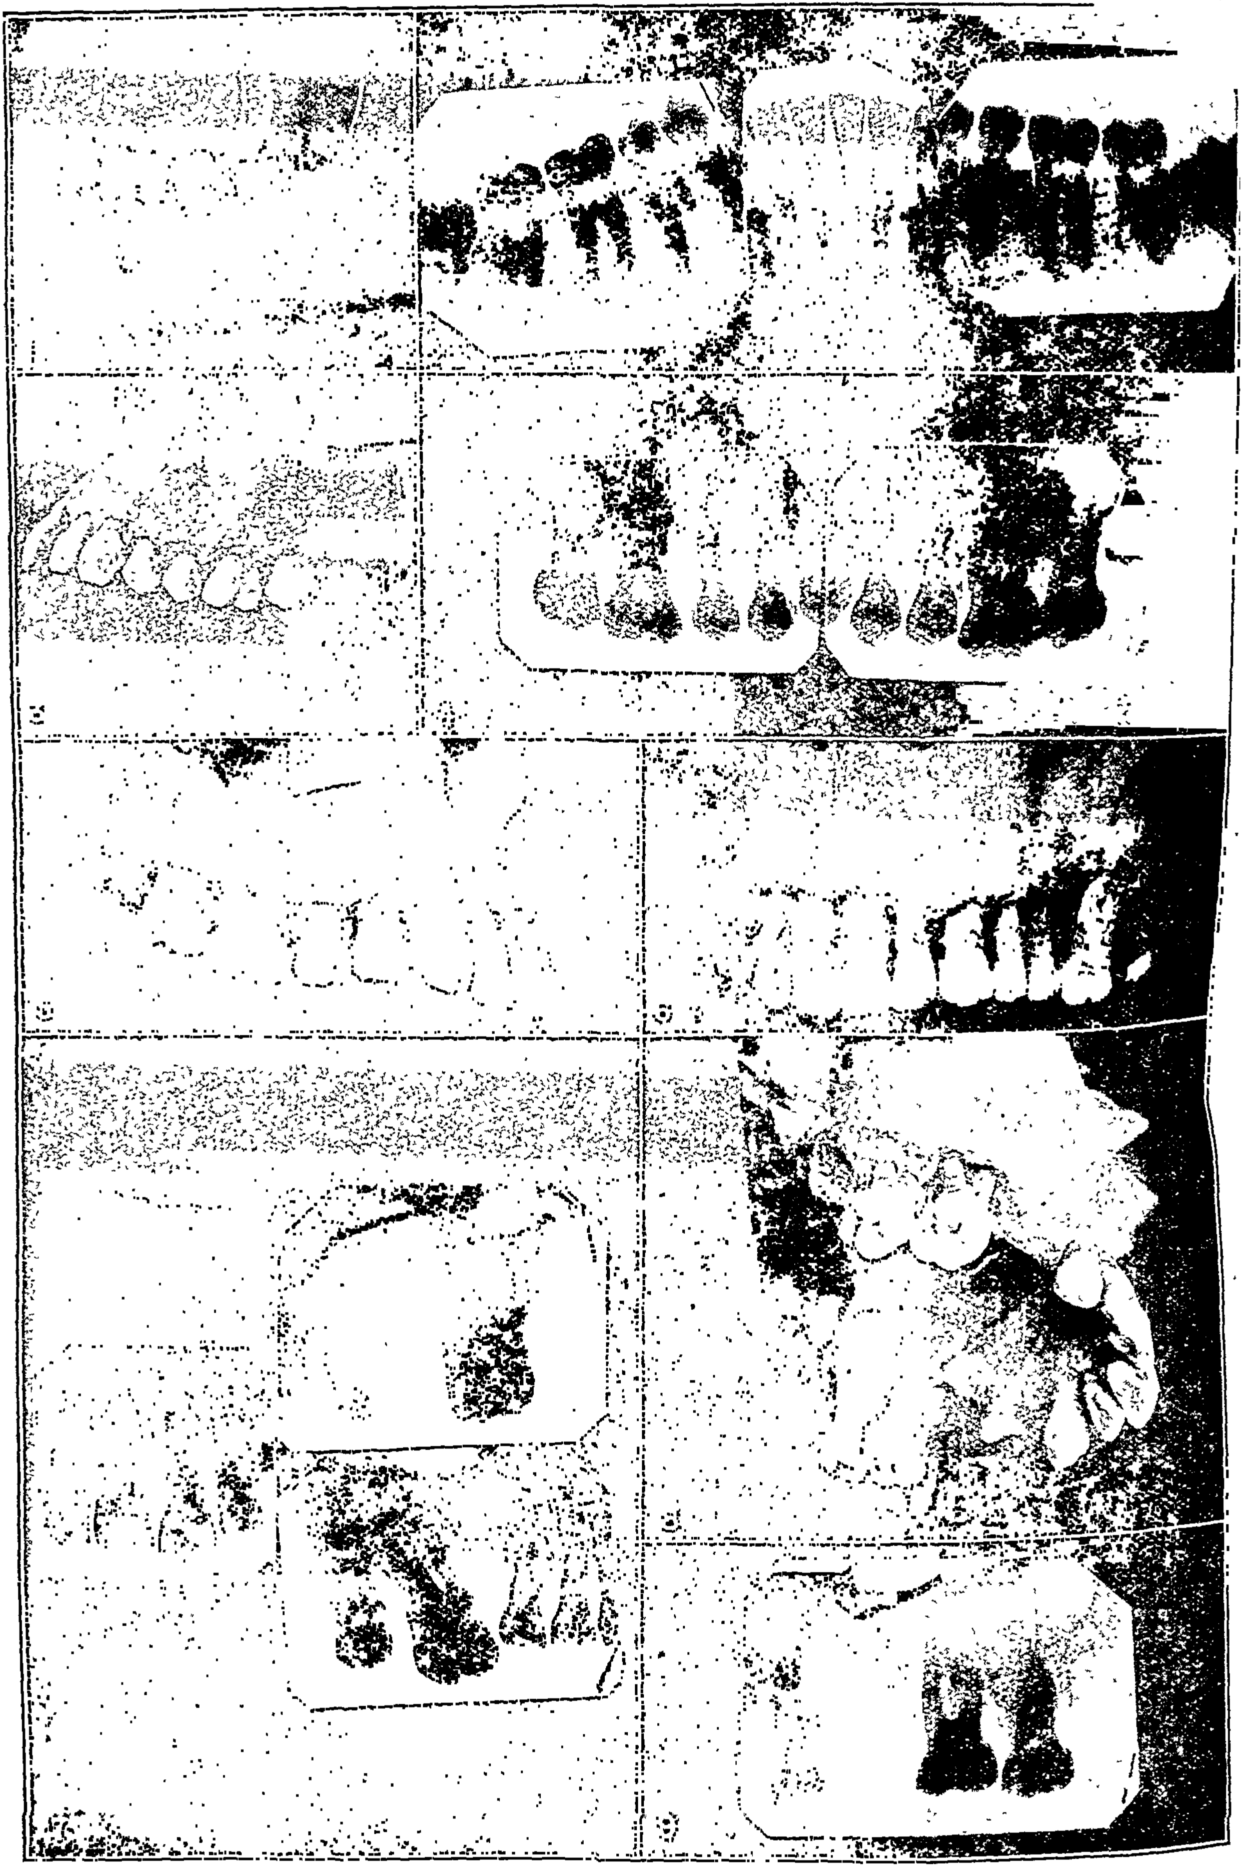

Fig. 3, a specimen which, casually observed, appears to be normal. Fig. 4 shows that destruction of the bone has lready commenced, as evidenced by the disappearance of the layer of dense tissue and the breach into the cancellous bone.

As the destruction of the bone advances the outer and inner plates of the alveolar process become involved, but the loss of tissue a[illegible] teeth than on the buccal and [illegible] in Fig. 5. [illegible] on of bone [illegible] pared with that around the [illegible] 2) the greater loss of tissue [illegible] that around the premolars.

The specimen shown in Fig. 6, from a male aged 30 years, shows in an excellent way the morbid anatomy of an advanced case. The bone around the incisors has almost disappeared, and the molar teeth are uncovered to near their apices. Cup-like spaces around the teeth are evident, this appearance being due to the fact that the bone bordering the tooth disappears first. The appearance of the bone shows that there has been a marked rarefying osteitis. Nodular deposits of calculus are present on the teeth, and it will be observed that these are in the case of the incisors, canines, and premolars well away from the margin of the bone. The skiagram of this specimen is shown in Fig. 7. The cup-shaped absorption of the socket is well seen in the right first molar of the specimen illustrated in Fig. 8. Around the second molar the destruction of the bone has been of a more chronic type, the cup-shaped absorption being absent. The skiagram of these teeth (Fig. 9) shows a very distinct difference. Around the roots of the first molar there is a definite clear area and an absence of the dense layer which marks the outline of the normal socket. The bone around the tooth shows definite signs of rarefying osteitis. The bone bordering the roots of the second molar still retains the dense appearance, and indicates that rarefying process has not spread deep into the bone around this tooth.

A point worthy of notice is the difference in spread of the disease in the maxilla compared with that in the mandible, and this is especially marked in the region of the molars. This limitation of area of the bone destruction in the mandible is of interest, and is to be accounted for by the different nature of the osseous tissues in these two bones. In the maxilla the bone is of a much more cancellous character than that in the mandible. This difference in the spread of the disease in bones of different density is, as we shall subsequently see, well brought out in considering the disease in the lower animals.

In the final stage of the disease the teeth fall out owing to extreme loss of the surrounding bone. The series of specimens just described indicates that the bone lesion is a progressive rarefying osteitis which commences at the margin of the tooth socket and eventually destroys the bone until the tooth is shed owing to the loss of its attachments.

Clinical experience shows that the disease varies in its rapidity, and that in some individuals there is a definite reaction of the periosteum of the bone to the injury from the toxins. This is shown by a general thickening of the alveolar bone and, in a few cases, by the formation of nodulated masses simulating exostoses.

The Teeth.

The teeth exhibit definite changes. The hard tissue shows absorption, and the periodontal membrane is thickened—indications of a chronic inflammatory process. Teeth removed from a series of cases are shown in Figs. 10, 11, 12. The teeth illustrated in Fig. 10 were from a man about 34 years of age, who was a mouth-breather and was suffering from mucous colitis. One year previously he had an attack of arthritis involving several of the large joints. The roots of the teeth showed signs of rapid absorption. The condition of the teeth may be taken as an index of the amount of rarefying osteitis. Let me explain this point more fully. Absorption of the hard tissues around the apex of the tooth indicates the [illegible] You cannot have periodontitis [illegible] in the adjacent bony tissue. [illegible] of the tooth the more extensive will be the rarefying osteitis, and the greater the degree of rarefying osteitis the greater will be the liability to direct infection of the tissues.

The molar teeth frequently show large masses of adventitious tissue in the cleft between the roots, indicating extensive loss of osseous tissue at these points. The specimens shown in Fig. 11 are very good examples of the condition of the teeth from cases *exhibiting deep pockets* and profuse suppuration. For two years treatment by vaccines had been tried, but the patient, who was suffering from marked septic poisoning, continued to "run down hill." The removal of the affected teeth, 14 in number, brought about a rapid improvement in health.

An examination of teeth removed from certain cases of periodontal disease indicates that with the formation of a pocket around the tooth pathological changes commence around the apex of the tooth. This is well demonstrated in the teeth shown in Fig. 12. In this case there was a persistent gingivitis, but as far as could be ascertained neither the pockets nor the bone destruction were very extensive. The teeth on removal showed that around the apices there had been active trouble, as evidenced by the absorption of the tooth tissue which had occurred. This condition can be explained as follows. From the septic focus around the neck of the tooth absorption of toxins or organisms takes place through the periodontal membrane, probably by lymphatics. The material absorbed is held up, as it were, in the tissues around the apex. In other words, there is probably a natural defence at this part of the tooth to prevent the organisms and toxins passing into the general circulation. With the arrest of the toxins, &c., the tissues around the apex naturally react to injury; that is to say, the phenomena of inflammation appear. The formation of these septic foci around the apices of the teeth has, so far as I know, not been recognised, but it is clear that it is an important factor to be reckoned with in considering treatment

2. THE DISEASE AS SEEN IN ANIMALS.

Periodontal disease is of frequent occurrence in horses, in cats and dogs, and in wild animals that have been kept in captivity. A study of the disease in these animals is most instructive, and throws considerable light on the ætiology and pathology of this serious affection. For convenience we may consider this section under two headings: (*a*) wild animals and (*b*) domestic animals.

(*a*) *Wild Animals.*

The odontological collection in the Museum of the Royal College of Surgeons of England contains a unique collection of skulls showing the disease in a wide range of animals. There are examples in rodents, marsupials, herbivora, monkeys, edentata, and the small and large carnivora. As an example, we may take a series of four specimens showing various stages of the disease in the kangaroo and its allies. An early stage is to be seen in a Bennett's wallaby (Macropus bennetti) (Fig. 13). In the maxilla the septa between the anterior teeth have been partially destroyed, and in the region of the first molars the bone shows signs of rarefying osteitis. A more advanced stage can be seen in the skull of a brush-tailed kangaroo (Petrogale penicellata) in the same collection. The disease here is more generally distributed, the mandibular teeth being more affected than in the preceding *specimens*. A slight deposit of calculus is present on the teeth. A skull of macropus (species unnamed) takes us a stage further. Here the bone has been extensively destroyed in the neighbourhood of the right maxillary third molar: the bone shows plenty of signs of rarefying osteitis, while in the mandible there is a marked thickening of the bone in connexion with the right first molar. Lastly, there is the left half of the skull and mandible of a kangaroo in which all the molars have been lost with the exception of one in the maxilla and one in the mandible. (Fig. 14.) The bone around both *these has been* extensively destroyed.

In the carnivora a similar gradational series can be traced, the point of interest being that the disease tends to spread more rapidly in the maxilla than the mandible, owing probably to the less dense character of the former bone. Among the suricates the mandible is more often affected than the maxilla; this is possibly to be accounted for by the fact that the shape and arrangement of the mandibular teeth favour food lodgment. In the museum there are several well-marked examples of the disease in the herbivora. An instructive specimen is shown movements which can aid in the localisation of the cause. Although in later infancy babies may insert their fingers into their mouths if they have sore gums, or may pull their ears if they have earache, or may give some other focalising indications of the seat of pain, during the first few months of their existence their only method of reflex response is to cry—an often expressionless cry—to flex their legs and arms on the body, and to tighten up the abdominal muscles. The diagnostic significance of these actions as indicative of abdominal pain is almost valueless in early infancy. They suggest, indeed, that the infant is in pain, but are no more indicative of pain in the abdomen due to colic or wind than they are of pain in the buttocks due to a pin or a crease in the napkin. But inasmuch as abdominal pain is much the most frequent form of pain in young infants, it can readily be understood why when an infant draws up its legs and hardens its belly it is reported to have stomach-ache, and why the diagnosis is so often correct.

An infant, however, cries for other reasons than because it is in pain. Crying, as I have already mentioned, is a protective reflex. A baby cries in the first instance because by so doing it benefits itself—for example, by expanding the lungs, attracting attention, or obtaining oxygen. The cry, however, may soon become a habit, and may continue long after it has ceased to confer any advantage. Let me give an instance. An infant is put into a bath which is too hot—the protective reflex is aroused, and it cries. Ever afterwards it cries in the same way when it is put into its bath, no matter what be the temperature of the water. The reflex has become a habit, although it has lost its original significance. The more one studies the habits of infants the more one learns to appreciate the importance of "suggestion" in the determination of their actions. Infants far more often cry from suggestion than they do from pain. Pain, it may be, was an associated and integral part of the original reflex, evoked by some particular stimulus, but the same stimulus at a later date, although not sufficiently intense to cause pain, will elicit a cry as an associated reflex. It is most important to be able to differentiate between the cry which is really due to pain and the cry which is due to habit, or which is the emotional concomitant of a compound reflex. The psychological analysis of the reflex actions in infants and of their habits is most interesting and instructive. The infant, before the development of the cerebral centres which are concerned in the perception of sensations, is in almost exactly the same case as an adult in a cataleptic or deep hypnotic trance. That is to say, the lower centres respond to sensory impressions without the interference of independent judgment, and the subject of them can perform complicated and habitual acts without being conscious of the fact. I could give you a great number of instances in which by the application of the methods of psycho-analysis it has been possible to arrive at the causation of many seemingly inexplicable habits in infants. If you have any reason for believing that an infant cries, or behaves in any particular way, from habit, you must review the past history of the infant with the greatest care to discover if possible the event or stimulus which first stereotyped the reflex. The line of treatment you then adopt will be dependent on the nature of your discoveries.

In any particular case in which you suspect an abdominal causation of pain it is necessary not only to exclude habit, but also to eliminate other central causative factors of crying. I would remind you that syphilis is a cause of constant crying in infants, but the same symptom also occurs in babies of unstable nervous systems, and may be due to other causes. The neurotic element may be suspected when there are sleeplessness, restlessness, hyperæsthesia, photophobia, hyperacusis, rigidity of the limbs, dilatation of the pupils, increased tension of the fontanelle, and slowing of the pulse. Proceeding with the method of exclusion, we should next attempt to eliminate the most common causes of pain outside the abdomen. These are dentition, middle-ear trouble, and external irritants. It is the fashion to minimise the importance of dentition as a cause of disturbance in infancy; but it must be remembered that, although the majority of the troubles due to dentition occur immediately before the eruption of the tooth, other reflex or irradiated disturbances are occasioned by sudden and irregular spurts in the development of the teeth, and consequently such may occur at unexpected moments. Pain and crying due to dentition may be recognised by certain concomitant vasomotor phenomena. A patch, or patches, of redness on the cheeks is most suggestive; effusion of the eyes, corneal ulcer, running of the nose, and, above all, localised areas of hyperæsthesia, are almost pathognomonic. Chvostek's sign, or the facial phenomenon, is, in my experience, far more reliable as a sign of the approaching eruption of the canines than as a diagnostic evidence of rickets. Tenderness of the external ear and eczema at the back of the pinna are highly suggestive of troubles in connexion with the cutting of the molars. Then as regards the middle ear: in my experience distension of the tympanic cavity is very common in infants, and with this distension and bulging of the membrane there is almost invariably severe pain. The infant rolls its head about, or maybe bangs it on the pillow, pulls at its ears, or even thrusts its fingers into the meatus. There is usually a history of a previously existing cough, and physical evidence of nasopharyngeal catarrh and adenoids may be present—conditions which account for the occlusion of the Eustachian tube and the consequent distension of the drum of the ear. Under such conditions the chain of glands running along the posterior border of the sternomastoid muscle are probably enlarged or shotty; sometimes the anterior cervical glands are alone enlarged. The diagnosis can be confirmed by direct examination of the membrane with the otoscope.

If we can exclude habit, general nervous excitability, dentition, ear trouble, and obvious external causes of irritation, such as pins, wet napkins, and creases in the clothing, as causes of crying, I think we shall be justified in suspecting that the source of the pain is localised in the abdomen, by far the commonest seat of pain in infants under six months of age.

As I have already indicated, in quite young infants there is little to distinguish the pain due to abdominal disturbance from pain due to other causes. In this, as in other painful conditions, the legs will be drawn up, the arms flexed, and the hands probably clenched; the recti abdominales will be tense and the abdomen hard. There may be areas of hyperæsthesia, but they are difficult to locate, as the infant may be more or less tender all over. With abdominal pain, however, the baby usually appears to be comforted by gently rubbing the abdomen or when laid face downwards on a pillow. Heat applied to the abdomen usually gives relief.

The causes of abdominal pain in their approximate order of frequency are as follows: 1. Dysperistalsis of the intestines, including enterospasm caused by irritation, obstruction, or nervous incoördination. 2. Disturbances of the motor functions of the stomach, including pyloric spasm, hour-glass contraction, spasm of the cardiac sphincter from wind, food, or other causes. 3. Incoördination of the motor functions of the bladder, spasm of the sphincter vesicæ, &c. 4. Referred pain from the thoracic cavity, pneumonia, pleurisy, empyema, &c. 5. Renal colic. 6. Spinal caries and osteomyelitis. 7. Peritonitis, appendicitis, &c.

Dysperistalsis or incoördination of the motor functions of the intestine, and chiefly of the colon or rectum, is undoubtedly the commonest cause of pain in infants. Indeed, in infants under six months of age it is a more frequent cause of pain than all other causes put together. I imagine, therefore, that I shall not waste the time placed at my disposal if I enter somewhat fully into the physiology and pathology of this symptom.

It has been a matter of considerable controversy among physiologists, pathologists, and neurologists whether or no the intestines are provided with nerves capable of transmitting sensations of pain. The work of Dr. Henry Head and Dr. James Mackenzie on this subject is well known. It is argued that the intestines do not possess pain nerves, because clinical evidence proves that they can be cut, lacerated, or pulled without the patient experiencing any symptoms of pain. On the other hand, we know that colic, enterospasm, and other forms of incoördinated contractions of the muscles of the bowel can give rise to exceedingly painful sensations. These painful sensations have been ascribed by Professor Wilms and others to the dragging and pulling of the nerves in the mesenteric attachments and not to stimulation by nerve ending in the bowel wall itself. Explanations of the pain of colic on such grounds seem to me most irrational. The simple explanation given by Professor C. S. Sherrington appeals to me much more forcibly. His explanation is that the sensory nerve endings in the intestines are to be regarded as highly specialised receptors, tuned or sensitised to receive one class of impressions only—namely, those which are of an essentially useful or protective nature. By a process of selective adaptation, both in the phylogenetic and in the ontogenetic sense, the appreciation of all other varieties of stimuli has been suppressed; those only are operative which are associated with dangers to the motor functions.

The motor functions of the intestines are so important to the well-being of the individual that it is obviously of paramount importance that there should be some nervous mechanism to regulate these functions. One essential element in such a mechanism must clearly be a highly sensitive series of receptors to keep the central nervous system in *rapport* with any event which interferes with the normal functions. Hence the sensory receptors turn a deaf ear to all other kinds of stimuli except those which are directly concerned with the motor function. It is through the instrumentality of these highly sensitised receptors that the infant acquires the power of conducting its intestinal motor functions with physiological efficiency. The moment any ill-coördinated contraction interferes with the smooth working of the motor mechanism, the infant's central nervous system is at once informed by the reception of painful impressions, and by a series of automatic and unconscious adjustments peace is restored. Thus slowly and with pain and tribulation the infant arrives at physiological perfection as far as the peristaltic functions of the bowel are concerned.

The mere fact that most of us are entirely unconscious of peristaltic movements which are constantly in operation, and which give us such excruciating pain when they are irregularly conducted, surely emphasises in a very marked degree the physiological efficiency of the method of peristaltic education during early infancy. When we contemplate the smoothness and regularity with which our intestines perform their daily functions we cannot grumble at the throes and pain we suffered in the early days of infancy. These pains are chiefly due to spasms of sphincters and to persistent localised contraction of the bowel musculature; the wave of contraction, instead of sweeping forward with the periodicity and regularity of a musical note, strikes disharmony into our system by coming to a sudden halt at some unexpected and inconvenient node.

Spasm of the pylorus and hour-glass contraction of the stomach are exceedingly common causes of abdominal pain in infants; they are reflexes which are distinctly protective in character, for they are clearly designed to shut off from the vulnerable intestinal tract indigestible or poisonous varieties of food which have gained entrance to the stomach. Abdominal pain due to pyloric spasm, or hour-glass contraction, can be recognised by the visible peristaltic waves which pass across the abdomen from left to right. These waves can be felt as well as seen, and the spasm of the pylorus can also at times reveal it[illegible] as a hard tumour in the region [illegible] appears as the spasm relaxes. [illegible] contraction, a pyloric tumour, constipation, and wasting are the classical symptoms of congenital hypertrophic pyloric stenosis, but they are also far more commonly the syndrome of a purely functional disturbance of the motor mechanism of the stomach—namely, spasm of the pyloric sphincter.

Spasm of the cardiac orifice of the stomach is in my opinion even more common than pyloric spasm; it gives rise to very considerable pain when air has been swallowed or generated in the stomach. Gripe waters and antispasmodics act by relieving this spasm and giving exit to the wind. It is quite as important that the stomach should learn to perform its duties in a business-like manner as that the intestines should acquire proficiency in their own particular motor functions. The receptors of the stomach are therefore highly sensitive to all those forms of stimuli which disturb its functions. Hyperacidity of the gastric contents, either from fermentation of the food or from over-activity of the acid-secreting glands, is a common cause of pyloric spasm. So is the ingestion of indigestible forms of food, especially during the first few days of life. Colostrum is the only food which should be allowed to enter the stomach during this period. Cow's milk, or even human milk, cannot be digested at this period, and therefore may induce spasm or incoördinated movements. The treatment of case[illegible] consist in correcting [illegible] the digestive capaci[illegible] spasmodics. Opium is the most valuable of all drugs, but it must be given carefully at first and then somewhat heroically. Brandy, chloric ether, and the bromides are also valuable, especially when combined with dill water, oil of cloves, or peppermint. If these simple expedients fail, the daily washing out of the stomach with a weak solution of milk of magnesia or carbonate of sodium will generally solve the difficulty.

As I have already indicated, dysperistalsis, or incoördinated contraction of the bowel musculature, is by far the most common cause of abdominal pain in infants; it may be regarded almost as a physiological fore-stage of normal and painless peristalsis. It is, however, very desirable that these necessary but painful experiences in the infant's educational curriculum should be as few and as short-lived as possible, for nothing is better calculated to disturb the development of the central nervous system than constant abdominal pain. It is, therefore, of considerable importance to study the best methods of teaching the bowel its natural functions and the best means of preventing the establishment of bad habits. I am convinced that one of the greatest safeguards against wrong methods of instruction is to leave Nature to work her own system. She has devised a careful method, and has provided in meconium a highly suitable material on which the bowel may practise its tyro efforts. In order that the musculature of the bowel may be excited to contract and perform its functions of peristalsis it is necessary that an adequate stimulus should be applied, neither too strong nor too weak, and this is of special importance during the first two or three days of life when habits are formed. Meconium supplies exactly the right sort of stimulus. It lubricates the mucous membrane and is sufficiently solid to form a very satisfactory motion, until such time as it is replaced by the ordinary constituents of an infant's stool.

I regret to say that it is a very frequent practice to sweep this valuable educational medium out of the bowel by a generous dose of castor oil. There can be no more irrational procedure. The castor oil is too strong a stimulus; it excites active peristalsis, and it deprives the bowel at one fell swoop of the didactic material which should last it for several days to come. The after-effects of this initial over-stimulation are reactionary fatigue and constipation, so that perhaps more doses of the purgative are administered before the incoming milk can supply the basis of a natural stool. In this way the natural rhythm and periodicity of the peristaltic function is interfered with from the very first, and the normal function is only subsequently established with much pain and crying on the part of the infant.

Abdominal pain due to the ill-coördinated movements of the bowel is not, as a [illegible] forms of abdominal c[illegible] always, accompanied [illegible] which may be too [illegible] abnormal. I cannot insist too strongly on the importance of examining an infant's motions carefully. They require to be well broken up and washed in a large quantity of water if their true character is to be revealed. When examined in this way they will often be found to contain a large quantity of inspissated mucus which has not been suspected. Those little white particles so often found in the stools of infants suffering from colicky pains, and which are usually described as undigested curds of milk, can be proved in this way to be composed of little balls of mucus and mucous membrane, which have been torn off the bowel wall and rolled up into the familiar forms as they are forced along the pain-racked lumen of the gut.

The pain connected with this form of peristalsis is usually intermittent; it often commences when the infant takes the breast or the bottle, for the movements of the stomach initiate the storm of waves which roll in disorder and confusion from one end of the intestine to the other. The violence of these pains often causes vomiting, and this vomiting has to be distinguished from vomiting of gastric origin. Vasomotor disturbances nearly always complicate the picture. The feet are cold the face looks drawn and bloodless, sometimes blue round the mouth, and beads of sweat often stand out upon the forehead. Other reflex or irradiated nervous phenomena may occur. The twitching of muscles and the drawing up of the legs are common symptoms, but general convulsions may also manifest themselves; these are usually inaccurately and inappropriately called "internal convulsions." Pain due to dysperistalsis is often relieved by pressure of the hand, by laying the infant on its stomach, or by hot applications to the belly. Massage along the axis of the colon often promotes the onward passage of a wave which has been fixed, as it were, in a localised spasm, and may then give instant relief.

If the points which I have already enumerated are remembered, no difficulty should be experienced in making a correct diagnosis, although we know well that such serious conditions of enterospasm as volvulus, intussusception, hernia, and constricting bands are occasionally mistaken for enterospasms of functional origin. Persistent and stercoraceous vomiting, a tumour palpable by the hand applied externally, or by the finger passed internally through the rectum, persistent constipation, or a muco-sanguineous discharge from the bowel, are diagnostic indications which can hardly be missed with the exercise of ordinary care.

A few weeks ago I saw an infant who was supposed to be suffering from an intussusception. The infant was, as a matter of fact, passing blood per anum, and was suffering from a severe attack of colitis. But colitis can hardly be mistaken for intussusception if the precaution is taken of making a digital examination of the abdomen per rectum.

Now, as regards the treatment of cases of abdominal pain due to dysperistalsis or enterospasm: excluding all those cases which have an organic basis, they may well be divided into the two classes—acute and chronic.

In acute cases energetic means of a nature we would not willingly repeat may be confidently applied. The chief desideratum is to relieve the spasm and keep the bowel at rest until the exciting cause has been removed. To effect these purposes there is probably no better treatment than the old-fashioned remedies, castor oil and opium. It is needless, I imagine, to remind you that care must be exercised in giving opium. I think that small and repeated doses, during which you can watch the effect, are much safer than one comparatively large dose. Tinctura camphoræ composita is a useful form in which to administer opium; one drop given every hour to an infant three months old is not likely to lead to much trouble. Brandy is always a useful antispasmodic, and may be given in 10–15 drop doses to an infant of the same age. All food should be suspended until the symptoms have subsided.

In the more chronic cases we are usually confronted with a vicious cycle of events; the nervous system is made irritable and explosive by the constant sensory impressions which reach it, and the dysperistalsis is encouraged by this very irritability of the nervous centres. It is important, therefore, to dull the excitability of the nerve cells by a nerve sedative such as bromide or opium, while the intestine should, of course, be relieved of all unduly powerful stimuli. The adjustment of the food is naturally one of the factors on which success most depends; cow's milk I regard as a powerful stimulus, especially in the unaltered state; completely peptonised it is less stimulating. Veal broth, whey, or even condensed milk, often help us to tide over temporary difficulties. The most valuable drug I know of in all these cases of irritability of the bowel is petroleum, and this best in the form of an emulsion. Petroleum soothes the bowel; it lubricates its surfaces, and it seems in some way to check decomposition.

Let me now pass on to another group of cases which certainly come under the same category of disturbed motor function. I mean those cases which are characterised by crying and evident pain whenever the infant passes urine. These cases are possibly more common in the case of boys than in that of girls, but in both they are common enough. I do not think, as a rule, the symptoms are dependent on acidity of the urine and irritation of the urethra as the scalding water passes over an irritable mucous membrane. The pain, I believe, is connected with incoördinated muscular contractions associated with the action of the sphincter vesicæ, and possibly with the muscles of the bladder itself; the pain is educational and protective. I only mention these cases because they are so common, and because they often give rise to a suspicion of stone in the bladder.

Renal calculi and concretions of urinary origin give rise to very severe symptoms in infants. The routine examination of the urine is the only means of avoiding mistakes in diagnosis. A short time ago I had under my charge a newly born infant. I took great care to avoid disturbing the peristaltic functions by unsuitable diet, but in spite of my care the infant evinced the clearest signs of abdominal pain. I could not believe that they were connected with the bowel functions, but for quite 24 hours I could not find any adequate explanation of the constant crying. At the end of that time the child began to pass large quantities of amorphous urates, which evidently gave the infant severe pain on their passage through the ureters. I have known several cases in which concretions have crystallised out of a concentrated urine, and I have found quite hard masses in the urethra which have necessitated removal by surgical interference. The pain of renal colic, due to obstruction of the ureters in the passage by calculi, is generally severe in infants; general convulsions often ensue, and there is nearly always evidence of some hyperæsthesia in the loins and back. The examination of the urine is, of course, the most valuable diagnostic guide under circumstances in which gravel is suspected.

Abdominal pain due to spinal disease, caries or osteomyelitis, often escapes diagnosis. The spine, however, should be examined as a matter of routine, and undue rigidity should always arouse suspicion. It is well to remember that lateral movements of the spine apparently cause more pain in spinal caries and osteomyelitis than forcible extension and flexion in the antero-posterior directions.

Pain due to appendicitis and peritonitis is not usually very severe in infants. Examination by way of the rectum is best calculated to reveal the existence of the conditions. Tuberculous peritonitis often runs a very chronic and unobtrusive course, and in my experience gives rise to very little pain.

The only way, after all, to appreciate the illusive symptoms of the impressionist baby is to live with it, or even to sleep with it. But pain must not be regarded as an unmixed evil; it is often a most valuable educational medium.

Harley-street, W.

EXTRADURAL ABSCESS AT THE APEX OF THE PETROUS BONE.

A COMPLICATION OF ACUTE INFLAMMATION OF THE MASTOID PROCESS; OPERATION; RECOVERY.

By HUNTER F. TOD, M.D. Cantab., F.R.C.S. Eng.,
AURAL SURGEON TO THE LONDON HOSPITAL.

An extradural abscess is the most frequent complication of acute inflammation of the mastoid process, being due to direct extension of the infective process through the bone to the outer surface of the dura mater, and is almost invariably found in the region of the tegmen tympani or of the lateral sinus, the latter being most frequent. In this particular instance the situation of the abscess at the inner part of the anterior surface of the petrous bone is so rare that I venture to publish the case in detail. Failure to discover such an abscess invariably leads to death from meningitis, usually from rupture of the abscess through the dura mater into the subdural and subarachnoid spaces of the posterior intracranial fossa; and necropsies proving this can no doubt be recalled by the majority of those who have had an extensive experience in aural surgery.

The history and subsequent treatment of the case are as follows. During the first week of April, 1912, the patient, a girl, aged 18, while at school abroad, had an acute attack of earache on the left side, accompanied by some tenderness over the tip of the mastoid. Within a day or two the drum perforated with considerable relief of the pain, and as there were no serious symptoms the medical man in attendance sent her home to England. The patient first came to me on April 23rd, three weeks after the onset of the trouble. There was a history of intermittent attacks of neuralgia of the left side of the face and for the last two weeks pain in the head, but there was no sickness or giddiness. The patient looked ill, and was dull and languid. Examination of the ear showed marked bulging of the tympanic membrane in the upper posterior quadrant, with a small nipple-shaped perforation from which exuded considerable discharge. There was also some slight tenderness over the tip of the mastoid. The patient was at once put into a nursing home. During the night the temperature was 100° F. and the pulse-rate 104.

Although the general condition pointed to the probability of the mastoid operation being indicated, paracentesis was first performed on April 25th. This seemed justifiable, as there was no pain over the body of the mastoid, and the drainage from the middle ear appeared to be insufficient. After paracentesis the temperature and pulse-rate at once became almost normal and the headaches and neuralgia disappeared. Within two days, however, there was further bulging of the membrane, with renewal of the symptoms. On April 29th the simple mastoid operation (Schwartze's) was performed. The extent of the disease was found to be much greater than had been anticipated. The cortex was dense; the antrum together with a large cell at the tip of the mastoid process were full of pus; and the bone was soft and hæmorrhagic, with dots of pus spreading through it, especially in the posterior group of cells surrounding the lateral sinus.

The operation was extensive, involving exposure of the outer wall of the lateral sinus for a considerable distance posteriorly, with complete removal of the mastoid cells. The opening into the aditus was enlarged, and at the end of the operation fluid could be syringed through it into the middle ear and out of the auditory canal. The wound cavity was lightly packed with gauze. Cultures taken from the secretion showed a pure growth of the pneumococcus.

The immediate result of the operation seemed satisfactory, the [illegible] within a week, and by the fourt[illegible] e heard at least 15 feet off. O[illegible] ere still occasional attacks of neuralgia on the same side, and on changing the dressings a drop or two of pus always oozed out from the depths of the wound just behind the aditus. Examination of the optic discs and of the general nervous system showed them to be normal.

By May 25th the symptoms were so slight and vague, and the amount of purulent discharge so minute, that I thought it permissible to allow the patient to return to the care of her medical attendant in the country, in the hope that change of air and tonics might do her more good than remaining in a nursing home, but he was warned that the case was not progressing normally, as by this time the purulent discharge ought to have ceased. On June 9th (six weeks after the operation) a letter was received from the medical attendant saying there was still some purulent discharge from the depths of the wound cavity which otherwise was quite healthy, and that the hearing seemed normal, but he added the following note: "Within a few days since she arrived she has been sick every morning when she gets up. It passes off, and she goes on all right for the rest of the day. [illegible] of the left side of the [illegible] her temperature sub- [illegible] but is still listless and [illegible]

On receipt of this I telegraphed for the patient to come to London. On June 10th, when I went to the nursing home to examine her, I found her lying curled up in bed on the opposite side, still complaining of slight pain over the affected side of the head, often referred to the eye, with attacks of nausea when she moved about. Examination showed the wound to be much smaller and to be healing well, but a drop of pus oozed from the depths of the wound on the removal of the gauze dressing. There was no nystagmus, and the reflexes and optic discs were normal. Next day the patient was anæsthetised and the wound carefully examined. Pus was found to exude drop by drop from a minute aperture in the tegmen tympani at its innermost margin, through which, however, a probe could not be inserted.

Further operation was then decided on in the expectation of finding an extradural abscess in the region of the tegmen tympani, but as the hearing was normal I promised the parents not to interfere with the tympanic cavity. For this reason the operation was limited to chiselling away the posterior wall of the auditory canal, with the exception of its innermost margin, together with the posterior part of the tegmen tympani. Unfortunately, the suspected extradural abscess could not be discovered even on raising up the dura mater from the underlying bone. The dura mater itself was slightly congested, but its surface was intact and pulsation was definite. The result of the operation was negative.

On June 13th (two days later) the patient complained of feeling sick and of pain in the left eye, but next day she was very much brighter, having no pain or vomiting, and retching less when moved. On dressing the ear no pus was seen to come from the wound cavity. On June 15th she seemed rather worse, being more drowsy, with a constant feeling of nausea, and she lay curled up in bed on the opposite side, having occasional periods of restlessness. It was obvious that there was still some undiscovered cause for these symptoms, and as there was nothing pointing to an intradural lesion it seemed certain that there was a collection of pus situated somewhere between the bone and the dura mater.

Mr. Charles Ballance and Dr. Henry Head were now called into consultation. Dr. Head confirmed that there was no optic neuritis, and that there were no symptoms pointing to an intradural lesion. Mr. Ballance also agreed with this opinion, and as pus was again oozing from the depths of the wound he supported my diagnosis of a deeply seated extradural abscess. Next day, June 16th (Mr. Ballance being present), I operated again, the remains of the posterior wall being freely removed, together with the outer wall of the attic, the malleus, and incus. The anterior portion of the tegmen tympani was then removed as far forward as possible, also the bone between the lateral sinus and semicircular canals, so as to expose the dura mater in the region of the posterior surface of the petrous bone. No extradural abscess could be discovered in this region. It was then decided to work forwards and to explore the inner part of the anterior surface of the petrous bone, even though it involved injury to the superior semicircular canal. The eminence formed by the superior semicircular canal was then cut away, which permitted the lifting up of the dura mater from the anterior surface of the petrous bone. As no pus could be seen, a blunt director was passed forwards downwards and inwards towards the apex of the petrous bone. After it had been inserted for nearly an inch over a drachm of thick yellow pus gushed out. Two fine rubber tubes were then inserted along the track of the director, and the abscess cavity flushed out with dilute hydrogen peroxide solution. The dura mater forming the roof of the abscess was somewhat thickened, and pulsation could not be felt. It was therefore incised for a space of half an inch, when some slightly turbid fluid escaped. A small rubber tube was then fixed into this opening by means of a suture, and the wound cavity lightly packed with gauze.

After the operation the patient was very restless and noisy, the pulse being 118 and the temperature 98°. Vomiting was incessant and was not relieved by a hypodermic injection of 1/6th grain of heroin. The patient lay curled up on the opposite side. As soon as she was conscious it was noticed that there was marked lateral nystagmus to the opposite side. The slightest movement caused the most intense giddiness and gave rise to the sensation that objects were going round in the opposite direction even when the eyes were closed. Next day the temperature was 99–99·4° and the pulse-rate 116–120 The patient lay motionless in bed, curled up in the same position, and objected to the slightest movement. Nystagmus was still intense and the vomiting so incessant as to prevent food being taken by the mouth, subcutaneous injections of ¼ grain of morphia in no way relieving it. Thirty-six hours after the operation collapse was extreme from general exhaustion. Improvement was obtained by means of saline injections and nutrient enemata. This treatment had to be continued for three days owing to the continued retching and vomiting. The patient still retained the same position of lying curled up in bed on the opposite side. The wound was dressed each day, when pus exuded freely from the deeply placed tubes.

By June 20th the general condition was improved, nystagmus being less intense when lying quietly, but there were still marked giddiness and nausea when trying to lift the head from the pillow; also the discharge from the tubes was becoming less. It was now possible to feed the patient by the mouth. She began to sleep better and to make spontaneous movements. On June 24th the tube was removed from the dura mater and the other drainage tubes were also removed, cleansed, and reinserted. The discharge had almost ceased. Next day there was a relapse, the patient being very depressed and inclined to be drowsy. There was also a recurrence of neuralgia in the head and of pain in the eye on the same side. The nystagmus and giddiness were less, but there was still marked vomiting on movement. The optic discs were examined and found normal. Next day there was no discharge from the tubes but the above symptoms had increased in intensity.

On June 27th there was increasing pain in the left eye. The drainage tubes were removed and the dura mater then raised from the surface of the bone by means of a spatula and a blunt probe inserted along the track of the tubes. About half a drachm of thick yellow pus escaped. Next day the patient was much better, although her general condition varied in an extraordinary degree, at one time there being considerable sickness with increase of nystagmus and at another complete freedom from pain or giddiness. By July 3rd the head symptoms, including vomiting and giddiness, had disappeared, and except for general weakness the patient was quite comfortable and could take light food. The wound looked healthy and on removing the tubes some clear fluid escaped in a slight amount. The dura mater was now seen to pulsate, which had not hitherto been noticed. Next day the tubes were removed. On the 7th the patient was allowed up for one hour, in spite of which there was no giddiness. From this time onwards an uneventful recovery took place, although until about the end of July there was still a tendency to giddiness if the patient made rapid movements or over-exerted herself. When seen in January, 1913, the following note was made, "The wound has now completely healed. The ear is in good position, the only external deformity being some depression behind the mastoid region which is concealed by the hair." Ever since December, 1912, the patient has been leading a normal life and enjoying society, including many dances. The hearing on the affected side is extremely bad, the voice only being heard when close to the ear. The high tuning-forks are not heard, showing that the internal ear is involved, the unavoidable result of the last operation during which the superior semicircular canal was injured.

Remarks.—The chief difficulty in the treatment of the case was the vagueness of the symptoms. Although the parents from the first pointed out that their daughter was usually of a bright and merry disposition, yet her dull and listless manner at the time of the first consultation was no more than might have been expected in the circumstances. At the same time, her intermittent attacks of drowsiness were sufficiently noticeable to be remarked upon by the nurses, although this was not brought to my notice until a later date.

After the first operation the unilateral headaches and attacks of neuralgia in the eye were so slight and so intermittent as to be almost neglected. Nevertheless, although no definite lesion could be discovered, one felt rather uneasy with regard to the progress of the case, because of the knowledge that after the simple mastoid operation the patient should be practically well with regard to her general condition within 48 hours; whereas the continuance of headache, neuralgia, drowsiness, or other such symptoms is always suggestive of some further extra- or intradural complication. With this feeling, but at the same time with the hope that the general condition might be due to the patient's temperament, and a suppurating cell the cause of the slight discharge and reflex symptoms, the patient was permitted to leave the home without further operation.

At the third operation it was necessary to remove the eminence of the superior semicircular canal in order to give more room to explore the innermost part of the anterior surface of the petrous bone. Before this was done it was found impossible to separate the dura mater sufficiently from the petrous bone. It was no doubt due to this anatomical fact that the abscess remained so localised and did not discharge itself more freely. The constant occurrence of headaches and neuralgia of the eye on the same side was probably due to irritation of the first division of the fifth nerve within the skull from the proximity of the abscess. Stoddart Barr has noted similar symptoms together with paralysis of the sixth nerve in connexion with suppuration of the cells at the apex of the petrous bone,[1] but in this case the cells were normal.

There was no evidence to prove the exact origin of the abscess, whether it was due to direct infection through the mastoid process, or through the tympanic cavity itself during the period of acute suppuration; but the fact that the head symptoms dated from the beginning of the illness and disappeared when the abscess was evacuated, only to recur again when it re-formed owing to imperfect drainage, points to its development even before the first operation had been performed. The complete absence of labyrinthine deafness up to the time of the last operation excluded internal ear suppuration. A blood count, if taken, no doubt would have shown marked leucocytosis, and further confirmed the diagnosis of an abscess. The difficulty, however, was not the diagnosis, but the situation of the abscess. The unilateral headaches and neuralgic pains in the eye rightly suggested the abscess to be located at the inner part of the anterior surface of the petrous bone.

The failure to discover the abscess at the second operation was due to the fact that the operation was limited in extent because a promise had been given not to injure the tympanic cavity, and consequently sufficient bone could not be removed. The knowledge that a suppurative lesion was present made me hesitate to separate the dura mater too forcibly from the underlying bone owing to the risk of injuring the meninges; this only could be done after the more complete operation, which involved removal of the eminence of the superior semicircular canal.

PNEUMOCOCCAL ABSCESS OF THE LUNG IN CHILDREN.

BY L. E. BARRINGTON-WARD, M.B., CH.B. EDIN., F.R.C.S. ENG. & EDIN.,
CASUALTY MEDICAL OFFICER, LATE RESIDENT MEDICAL SUPERINTENDENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

THREE varieties of acute abscess of the lung are met with in children. There is the abscess which arises from the presence of a foreign body in the bronchus; the multiple abscesses often following broncho-pneumonia and debilitating illnesses which are found scattered throughout the lung, which are due to a variety of organisms and which are not amenable to surgical interference; and the single abscess due to the pneumococcus with or without a preceding lobar pneumonia. It is as an instance of the last, the least common variety, that I narrate the following case.

A boy, aged 6 years, was admitted into the Hospital for Sick Children, Great Ormond-street, on Nov. 14th, 1911, under the care of Dr. A. E. Garrod. From the parents it was ascertained that he had been in excellent health until five weeks before admission. *His illness* began with what was described as a bilious attack. He became feverish, suffered from pain in the side, and developed a severe cough. He wasted rapidly and became pale and ill. The vomiting attacks became more frequent, the vomit being described as resembling phlegm. He had developed a well-marked lateral curve of the spine since the onset of the illness. His previous health had been good and the family history was unimportant.

On examination the most striking features were the pallor of his appearance and the curvature of the spine in the dorsal region with the convexity to the left. There was no dyspnœa, no cyanosis, no clubbing of the fingers, and no glandular enlargement. The tongue was furred and the breath was rather offensive. Perspiration was excessive. The temperature was 100·2° F., the pulse was 152, and the respirations were 32. The movement of the right side of the chest was deficient. The right base was dull on percussion. There was no Grocco's triangle on the left side. Over the dull area the breath sounds were tubular in the upper part, faint but audible in the lower. The vocal resonance was rather ægophonic. There was no cardiac displacement, the apex beat being in the fourth space in the left nipple line, and there was a systolic murmur to be heard in the pulmonary area. The abdomen was somewhat tumid. The liver and spleen were not palpable, and no mass could be felt. The blood count was as follows: hæmoglobin, 80 per cent.; red corpuscles, 4,408,000; and leucocytes, 21,500. Differential count: polymorphs, 84 per cent.; large [illegible] 0·5 per cent.; large lymphocytes, 6 per cent.; small [illegible] t.; and eosinophiles, 0·5 per cent. The diagnosi[illegible] de, but exploration in two interspaces over the [illegible] On Nov. 16th a radiogram of the chest was ta[illegible] Bruce. He reported: "To the right of the heart opacity is an area of evenly distributed increased opacity to be seen, obscuring the inner portion of the right diaphragm and possessing a sharply defined margin above and a diffuse one externally. It suggests a localised collection of fluid in the right pleural cavity towards the midline and base. Not much real displacement of heart, probably some rotation and apparent displacement on account of spinal curvature."

Despite the negative results of exploration, the blood count, the [illegible] of the boy so strongly suggested the [illegible] to open the pleural cavity to see the [illegible] chloroform was administered, and at [illegible] e right lung in numerous directions with the needle, but no pus could be detected. I therefore excised part [illegible] The opening was just above the dome of the [illegible] ed lung was lying upwards and inwards away [illegible] o adhesions of any kind were present, and the pleura appeared everywhere quite normal. The oblique fissure was [illegible] ing dependent and [illegible] withdrew a syringeful of pus. It [illegible] the wound was sewn up in [illegible] Part of the sixth rib was [illegible] Exploration of the lower [illegible] a distance of 1½ in. again [illegible] an attempt was made to [illegible] er with thick catgut. The [illegible] owing to the depth from the sur[illegible] patient its exact limits could not [illegible] tube was inserted and the gauz[illegible] was greenish-yellow, odourless, a [illegible] pneumococcus. [illegible]

[illegible] healed in four weeks. A well-marked lateral curvature of the spine persisted.

This case presents, I think, certain features of interest. A lateral curvature of the spine is not uncommon in chronic pulmonary conditions, but it occurred rapidly in this patient, and it was on account of this curvature that the parents sought hospital advice. The diagnosis was always difficult. The physical signs could have been accounted for by an unresolved pneumonia with fibrosis of the lung, by an empyema of some duration, or by an abscess in the lung. The polymorph leucocytosis, the pallor of his appearance, the perspiration and e[illegible] ture were in favour of [illegible] empyema was made. [illegible] was negative. A more thorough examination under an anæsthetic was also negative. It then seemed as though the deductions from the clinical signs were at fault and that the condition must be one of fibrosis, but Dr. Garrod decided that an opening into the pleural cavity should be made for more thorough examination. This was done, but the pleura was everywhere normal in appearance, and the lung on palpation felt peculiarly solid. It was as a last resort before closing the wound that a needle was passed into the lung itself and made the diagnosis.

The question then arose whether this collection was intrapulmonary or extrapulmonary—an encysted empyema. If an encysted empyema it could only be a large one arising in connexion with the mediastinal pleura and bulging outwards into the lower lobe. The interlobular fissure was demonstrated to be free from adhesions; the diaphragmatic pleura was seen to be unaffected; and it was necessary to bore through the lung itself to reach the pus. The coughing up of pus during the manipulations and again some days later, taken with the situation of the abscess, convinced me that this was a true intrapulmonary collection.

It is interesting to consider the radiogram in the light of what was found at the operation. Dr. Ironside Bruce reported that it suggested a localised collection of fluid in the right pleural cavity towards the mid-line and base. This was exactly the situation of the abscess. The failure to find pus on exploring with a needle must have been due to the depth of the abscess from the surface. It is an indication that too much stress should not be laid on a negative result if the general condition strongly suggests otherwise. Most writers on the subject have remarked that the exploring needle in cases of abscess may not be of assistance in arriving at a positive diagnosis. It is safer if there are reasonable grounds for suspecting the presence of pus to open the chest and examine the lung directly.

With regard to the treatment it is generally advised that the operation should be performed in two stages: at the first packing is introduced to create adhesions between the visceral and parietal pleura, and at the second the abscess is opened and drained. In this case the toxæmic condition of the patient demanded that relief should be given without delay, and happily no ill-effects resulted from the immediate opening of the abscess.

Acute pneumococcal abscess of the lung in children appears to be rather rare, and most of the works on the diseases of children hardly notice it. The literature is scanty, and those cases which have been reported have usually been the successful cases. I believe that an examination of post-mortem records would bring to light many more cases. Eisendrath[1] in 1901 collected 25 reported cases of acute abscess of the lung following pneumonia, and of these nine were in children under the age of 12 years. All these recovered after operation. Holt[2] has seen three cases, one at necropsy and two after successful operation. Hilton[3] estimates the mortality at 50 per cent. in a review of 15 cases, but in these the age was not stated. The post-mortem records of the Hospital for Sick Children, Great Ormond-street, contain *six cases only of pneumococcal abscess* of the lung. Four of these cases had an empyema also. Four cases were operated on, but in only one of these was the underlying abscess detected. In four cases a diagnosis of empyema was made. In the remaining two the [illegible] ot vary greatly. In [illegible]; in the others the pleural cavity was either obliterated by adhesions or distended with clear or purulent fluid. In three cases there was a definite natural communication between the abscess and the pleural cavity. The right lower lobe was affected in three instances, the left lower in two, and the right upper in one. The size of the abscess cavity varied from a small excavation 1 inch in diameter to a large necrotic sac which had replaced the entire lobe. The larger cavities were divided by septa which contained the subdivisions of the bronchi. In only one case was there a communication between the abscess and a bronchus. In each case where an empyema was present the evidence seemed to show that the abscess was primary. Considerable destruction of lung tissue would be present while the empyema would appear to be of fairly recent origin.

The age of the children is noticeable—four were one year and under, one was 3½, and the oldest was 6 years of age.

I think it must be conceded that pneumococcal abscess formation is a possible mode of termination of a lobar pneumonia. The origin of this type of abscess appears to be in a patch of pneumonia, which instead of resolving after consolidation becomes the seat of pus formation. In fact, the pneumococcus takes on an action which is common to it in other parts of the body, but is rare in the lung itself. Possibly the age and resistance have a bearing on this point. Guinon[4] describes the case of a boy of 4 who succumbed to a pneumococcal abscess of the lung not recognised before necropsy, and suggests the name of "hépatisation grise supparée" for the process. It is quite possible that many [illegible] ess [illegible] ch [illegible] or [illegible] I am very much indebted to Dr. A. E. Garrod for allowing me to operate on and publish this case.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN: UNIVERSITY OF LONDON.—Mr. F. D. Acland, M.P., has accepted the chairmanship of the council. The Dr. Edith Pechey Phipson post-graduate scholarship, of the value of £40 for one, two, or three years, will be awarded in June. Applications must be sent by May 31st to the secretary, from whom all particulars can be obtained. Entrance scholarships of the value of £60 for three or five years, £20 for four years, and £30 will be awarded on the result of an examination to be held on July 22nd and following days. All particulars can be obtained from the secretary. The Agnes Guthrie bursary for dental students of the value of £60 will be awarded in September.

A CASE OF

PERIOSTEAL SARCOMA OF THE FIBULA WITH UNUSUALLY RAPID THOUGH TYPICAL COMPLICATIONS.

By F. J. WADHAM, M.R.C.S. Eng., L.R.C.P. Lond.,
SURGEON TO THE ROYAL ISLE OF WIGHT COUNTY HOSPITAL;
AND
E. L. HORSBURGH, M.B., B.S. Lond.,
HOUSE SURGEON TO THE HOSPITAL.

THE patient, a girl, aged 20, was first admitted to hospital on August 6th, 1912, with a history of pain and slight swelling in the left knee of three months' duration. Up to that time she had always enjoyed excellent health and had followed her occupation of housemaid without difficulty. There was no history of injury or loss of weight. Examination revealed a swelling of about the size of a hen's egg over the upper end of the left tibia. It was hot and tender to the touch. It was firmly fixed and non-fluctuant. No eggshell crackling was obtained. The head of the bone was not apparently expanded. X rays showed the head of the fibula enlarged with broken outline. Spicules of bone were seen in the middle of the growth. A diagnosis of periosteal sarcoma was made. On August 8th a flap amputation in the middle of the thigh was performed. The growth was examined microscopically, and the following report was furnished by the pathologist: "This is a malignant growth, having the structure of a sarcoma. It is composed of large round cells and spindle cells, and is infiltrating and destroying striped muscle. I conclude it is a periosteal growth."

The patient recovered from the operation extremely well and a primary union was obtained. She was, however, kept in the hospital for observation until Oct. 4th, when she left apparently free from recurrence. She presented herself next at the out-patient department on Nov. 26th, complaining of pain and stiffness in the left groin. Examination showed a firmly fixed, stony hard mass in the left iliac fossa. Masses were also felt in the saphenous ring and following the course of the femoral vein upwards. Recurrence was diagnosed, and the patient was readmitted, but no operation could be undertaken. The patient, beyond the pain in the groin, was very well, got about on crutches with ease, and had not lost any weight. As it was considered useless to detain her in hospital she was discharged on Dec. 8th, 1912.

On Dec. 19th the patient again presented herself at the out-patient department suffering from most urgent dyspnœa and cough. Examination showed the left chest to be immovable; absolute dulness front and back up to the clavicle. The heart apex beat was in the right nipple line and breath sounds were quite absent. Nothing abnormal was discovered in the right chest. Fluid was diagnosed, and the chest was aspirated below the angle of the scapula and two pints of sanguineous fluid were withdrawn. The symptoms were relieved. The displacement of the heart persisted; the apex beat was now half an inch internal to the right nipple line. The fluid gradually reaccumulated, and the patient's general condition became so bad that further aspiration was deemed inadvisable. She gradually sank and died at 8 30 A.M. on Dec. 30th.

Necropsy.—The thorax and abdomen were opened in the usual way. The left chest contained more than a gallon of blood-stained fluid. When the pleura was swabbed dry it was seen that the left lung was completely collapsed and full from apex to base of solid growth which cut like cartilage. The growth appeared to follow very closely the bronchial tree. The right lung was also studded throughout with recurrent nodules, the largest size being about that of a two-shilling piece. There was, however, a considerable amount of normal lung tissue, but there was no evidence of emphysema. The pleura on the left side was covered with hard growth, which was heaped up to the extent of quite half an inch from the serous lining. Scarcely an inch of the pleura was unaffected. The visceral pleura was affected on both sides, though chiefly on the left. The pleural surface of the diaphragm was covered throughout with growth, though here it was in places heaped up to quite an inch in height. The recurrence in the groin was then examined. There was a mass of stony, hard growth all round the saphenous vein, surrounding also the femoral vein, the external iliac vein, and some way up the inferior vena cava. The circumference of this recurrence all the way up was about the size of the closed adult fist. There was considerable œdema of the amputation stump in consequence of this.

The case is, we think, of interest: (1) in proving the intense malignancy of these tumours; (2) in the typical distribution of the metastatic deposits *viâ* the blood stream to the lungs; (3) from the complete lack of symptoms of recurrence till just at the end of the illness; (4) from the post-mortem examination, which showed an astounding amount of growth for the length of the history; and (5) from the intense rapidity of the sequelæ.

A NOTE ON

THE USE OF SUGAR IN HEART DISEASE.

By STANLEY E. DENYER, C.M.G., M.D. Cantab., F.R.C.S. Eng.

PHYSIOLOGISTS have experimentally proved the nutritive value of sugar upon heart muscle. It has been established clinically that it undoubtedly gives good results in some forms of heart disease. In other forms no benefit has been observed from its use. The only way to get a classification of the value of remedies is to put on record the cases we treat with those remedies, both the failures and the successes. The failures are apt to be unrecorded, as they do not cause so much interest as the successes, but they are quite as important for statistical purposes. From the few inquiries that I have made, cases with œdema, cases with anginal pain, and cases where cardiac disease is secondary to renal disease do not seem to be improved by it. In a case of general paralysis of the insane, where the pulse was failing, I tried sugar, but it had no effect. In the following case the effect was so marked that I feel sure the patient's life was saved by it. The clinical history is as follows.

The patient, aged 77 years, had an irregularity of the pulse for some years. On Nov. 8th, 1912, she had a bad heart attack, with rapid, irregular, feeble pulse, cyanosis, and attacks of paroxysmal breathing, which occurred about 5 or 6 A.M. There was no œdema at this time, nor at any time during the illness. I saw the patient at 7 A.M. and ordered inhalation of amyl nitrite, which gave temporary relief. This condition continued for some days, the patient steadily getting worse in spite of digitalis, digitalin, strychnine, dry-cupping, leeching, and frequent inhalations of oxygen. She said that the dry-cupping gave a great sensation of ease in breathing, and the oxygen certainly did her a lot of good, but the improvement was only temporary. On the 14th the patient seemed to be dying; when seen at 11 P.M. it seemed doubtful if she would live through the night. Her relatives thought even worse of her and were firmly convinced that she was going to die, and an experienced nurse whom I had in charge of the case thought there was little hope. I ordered some lumps of ordinary white sugar to be given in milk, and added some syrup to her medicine, telling them to give her four ounces of sugar during the night. In the morning I found the patient very weak, but less cyanosed and with a stronger, slower pulse. Digitalis had been omitted as well as digitalin, as these had not any effect on the heart or pulse. Four ounces of sugar were ordered during the ensuing 12 hours, and after that it was continued in smaller quantities for some weeks. The patient made a slow but steady improvement, the breathing attacks getting less frequent and the pulse stronger and more regular. Her general weakness was very great and she gained strength only very slowly. By the end of February of this year she was able to go out into the garden for a few minutes, and to walk up and down stairs.

ROYAL SOCIETY OF MEDICINE.

SPECIAL MEETING OF FELLOWS.

Discussion on Alimentary Toxæmia.

A SPECIAL meeting was held on April 14th, Sir FRANCIS H. CHAMPNEYS, the President, being in the chair.

Mr. J. B. LAWFORD said that during the last few years toxæmia due to disordered conditions of the alimentary tract had been widely accepted, not only as a possible, but as a probable, cause of certain forms of disease of the eye and its adnexa. Although proof was still wanting that the toxæmia and the ocular lesions were cause and effect, much evidence in support of this view was available in the records of carefully investigated cases. General agreement obtained that the ocular tissues most liable to suffer in toxæmia were the uveal tract and the corneosclera; some writers also included the ocular nervous [illegible] especially prone to involvement. [illegible] oral sepsis, especially when due [illegible] orrhœa alveolaris, to inflammatory affections of the eye was almost certainly established. The ocular disease was most commonly a chronic iridocyclitis of a mildly plastic type, but choroiditis, usually localised and exudative, was also met with. Iritis in association with septic conditions of the tonsils had been recorded. The fact must not be overlooked that the large majority of individuals in whom pyorrhœa alveolaris and other varieties of oral sepsis were present did not suffer from irido-cyclitis, and also that irido-cyclitis with precisely similar characteristics was met with in patients whose mouths and teeth were above suspicion. Recurrent forms of episcleritis and sclero-keratitis had also been attributed with reasonable probability, to oral sepsis. These cases were, however, less common, and in his experience more doubtful in their etiology than those of the irido-cyclitis group. It was common knowledge that syphilis, rheumatism, gout, gonococcal infection, &c., had failed as a satisfactory explanation of many cases of ocular inflammation. In recent years enterogenous toxæmia had been invoked as the causal agent in these etiologically obscure cases. The occurrence of iritis, irido-cyclitis, and choroiditis in patients in whom there was evidence, especially from examination of the urine, of intestinal putrefaction, and in whom the above-mentioned causes could be excluded, led support to this hypothesis. Moreover, the improvement in the ocular lesions which often followed treatment of the intestinal derangement tended to confirm the diagnosis. That affections of the optic nerve might be caused by alimentary toxæmia had been suggested by some observers and discredited by others. Retro-ocular neuritis, the etiology of which was often very obscure, might be one of the results of auto-intoxication, and cases were on record which were less easily explained by any other theory. The possible etiological relation of auto-intoxication to infective processes in eyes recently operated upon was one deserving the closest attention of ophthalmic surgeons.

Dr. J. C. G. LEDINGHAM, whose paper will appear in a future issue of THE LANCET, said that his interest in the question was naturally confined to the bacteriological and biochemical evidence advanced by the school of Metchnikoff in support of their master's thesis, which asserts that the poisons elaborated by the micro-organisms of the intestinal tract, and particularly those harboured by the large intestine, are the most potent factors in the production of a long array of symptom-complexes loosely grouped under the term "auto-intoxication," and further that these same poisons are the essential causes of the sclerotic changes in the organs which accompany old age. Mr. Ledingham discussed the main bacteriological evidence which Metchnikoff and his pupils have brought forward during the past four years in support of the theory of intestinal intoxication. This evidence had been sought for in the following types of research: (1) an investigation of the flora of the large intestine or of the fæces with a view to the classification and identification of the various bacterial groups and their biochemical properties; (2) experiments on the toxic action of filtrates of special groups of these micro-organisms in animals; (3) analogous experiments with substances of definite chemical composition, especially indol; and (4) alteration in the intestinal flora as the result of food changes, constipation, and operations undertaken for the removal of the large intestine.

Dr. JAMES GALLOWAY spoke of the Cutaneous Indications of Alimentary Toxæmia. He said that the poisons capable of producing toxæmia resulting in these manifestations of disease seemed to come from two sources: first, those contained in the food itself or arising from the food by the action of ferments in the alimentary tract—these ferments might be those normally produced by the various accessory glands or might have some abnormal origin owing to disease or other causes; secondly, those resulting from fermentative or putrefactive processes due to the action of organisms which might be normal denizens of the alimentary tract or interlopers. Most of the external manifestations seemed to be more easily traceable to the first group of poisons than to the second, though this might very possibly be due to the fact that the noxious consequences of the action of many of these organisms, such as bacteria, were more difficult to appreciate and to trace to their original source. The outward menifestations grouped themselves easily in four main categories: 1. Those resulting from disturbances of the blood-vessels which disappeared leaving no permanent trace. 2. Morbid conditions in which an inflammatory lesion progressed to actual infiltration of the integuments with cellular elements and terminating in persisting deformity, such as dilatation of blood-vessels, atrophy, persistent dermatitis, ulceration, and scarring. 3. Purpura in its different forms—punctate, diffuse, and often associated with other hæmorrhagic manifestations. 4. Pigmentation due to increase or abnormal distribution of pigments closely related to those of the normal type, such as melanin, or in other cases to pigments more recently derived from hæmoglobin and due to hæmolysis resulting from the circulating intestinal toxins. 1. Of the first group, the various forms of simple or acute urticaria were by far the most common. The relationship between the ingestion of an unusual article of food, such as shell-fish or certain fruits, with the consequent outburst of urticaria, was so close as to leave no reasonable doubt that the poisonous material was contained in the ingested substance, or was very easily elaborated from it by the digestive ferments. A little more difficulty was felt when dealing with other varieties of the disease, such as the recurring type of urticaria, in which the lesions were usually not so severe or extensive as in the acute single attack, or the chronic variety, in which the lesions were usually diffusely scattered, though not large individually and left indurated lesions, giving rise to the term "papular urticaria." The relation between the various forms of erythema and alimentary toxæmia was more obscure. That such a relation did exist was borne out by the clinical experience of the causation of some of the simpler forms of erythematous eruption. The types of erythema exudativum in which, in addition to dilatation of the capillaries, escape of the contents of the vessels occurred into the tissues—either the blood serum or the blood cells—were by far less common than the simple erythemas. They were less likely, therefore, to observe the association between eruptions of erythema exudativum and affections of the alimentary tract, but that the relationship did exist in many cases was more than probable. The general impression given by clinical observation of this group of external manifestations was that the urticarial type was more frequently produced by the direct absorption of noxious ingesta or as a consequence of the more simple chemical changes in foods occurring in the upper portion of the alimentary tract from the action of the natural alimentary ferments; while eruptions of erythematous nature more frequently arose from affections of the intestines, especially the large intestine, in which the terminal processes of digestion took place, the poisonous materials involved being of a more subtle character, or perhaps due to the results of fermentations produced by bacteria or other organisms. The purpuric types of erythema seemed especially to indicate that the changes occurred in the colon or large intestine. 2. Closely allied to these lesions were certain others in which, in addition to the erythematous condition, tissue changes occurred. Of these the criterion was the appearance of new cellular elements—neither red blood cells nor white blood cells, but newly formed cells, characteristic of various types of inflammatory infiltration. The type of this morbid state was the disease usually known as lupus erythematosus—a condition closely resembling in its distribution erythema multiforme, but terminating in some degree of destruction or atrophy. The etiology of this mysterious affection was by no means well understood, but its connexions with visceral disturbances should never be overlooked. A good deal of attention had been drawn to its peculiar relationship with certain forms of disease of the kidney. In other cases a poison arising from the alimentary tract might be suspected of being the cause. 3. The probability of alimentary toxæmia being the cause of certain cases of purpura had long been recognised clinically, for the connexion between the outburst of purpura and the disturbance of the alimentary canal was sometimes as close as the outburst of urticaria following the eating of some unusual article of food. Many purpuric lesions arose no doubt by a peculiar development or simply by intensification of the conditions already noted producing erythema. They formed, however, on account of their aspect so characteristic a group that they claimed special attention. One of the most remarkable conditions in which the connexion between poisoning from the alimentary tract and the outburst of purpura was shown was in certain stages of hepatic cirrhosis. Another variety of purpura presented small hæmorrhagic areas of petechial or punctiform lesions. The relationship between this condition and alimentary toxæmia was very distinctly shown in Henoch's purpura. The same type of purpura was very familiar in association with chronic inflammatory conditions of the colon, such as the varieties of colitis and dysentery. The attacks were especially prone to appear when other evidences of toxæmia or septicæmia became prominent. There were grounds for associating the type of purpura characterised by large areas of cutaneous hæmorrhage with absorption of poisons from the upper part of the alimentary tract. These poisons might arise from infected food materials or might be produced by the normal, or only slightly abnormal, processes of intestinal digestion. The petechial and punctiform types of purpura, on the other hand, appeared to occur as the result of the terminal digestive changes or abnormal fermentative processes occurring in the lower reaches of the bowel, possibly influenced by the micro-organisms present in the alimentary tract. 4. This group included the abnormalities of pigmentation. The unhealthy, dusky discolouration of the skin occurring in various forms of indigestion was a matter of ordinary observation. Much attention had been drawn in the course of this discussion to the discolouration occurring in the cases of disease to which the name of intestinal stasis had been applied. It was difficult to be quite sure of the exact nature of this pigmentation. It was partly due, no doubt, to disturbances of the circulation producing unusual conditions of opacity or translucency of the skin, but in other cases, no doubt, it was due to a definite increase in the amount of the pigments identical with, or nearly related to, the normal skin pigment. The cases, however, which were most striking were those in which the pigmentation was due to unusual or abnormal pigments. The first to which reference should be made was the hæmolytic, or "urobilin jaundice," well seen in the severer forms of anæmia, many of which were associated with septic disorders of the alimentary tract. The most striking of all the varieties of abnormal pigmentation was seen in the cases to which the name of "hæmochromatosis" was given. The relationship between some of these cases of hæmochromatosis with poisoning arising from the alimentary tract was very close. In this category might also be included the cases of discolouration due to alterations in the hæmoglobin to which the names of "methæmoglobinæmia" and "sulphæmoglobinæmia" had been applied. In many of these abnormal pigmentations the relationship to alimentary toxæmia was a close one—probably that of cause and effect.

Dr. A. MANTLE (Harrogate) said that large numbers of functional disorders of the alimentary canal found their way to Harrogate from all parts of the world, and amongst them many were seen with symptoms which he thought were rightly considered as due to absorption of toxins, the symptoms varying with the particular tissues affected. They must have a picture in their mind's eye of the mucous tract from the naso-pharynx to the rectum, for they were dealing with a mucous disorder, and an endeavour must be made to localise the source of the infection. The paramount importance of a mouth being free from septic organisms was by no means fully recognised by the doctor or dentist. He therefore carefully examined the teeth and the mucous membrane of the mouth, tonsils, and nasopharynx, for careful investigations of apparently trivial infections of the mucous membrane of the nose and tonsils had explained the cause of many cases of rheumatoid arthritis He next examined the stomach and inquired for any symptoms of gastritis due to oral sepsis, and examined for dilatation, knowing that stasis of its contents with fermentative changes led to auto-intoxication. The most common form of alimentary toxæmia was due to constipation with catarrhal inflammation of the colon, for the stasis of the fæcal contents of the colon was favourable to bacterial multiplication and possible absorption of toxins. Absorption, however, did not usually take place unless there was a weak mucosa possibly with abrasions or ulceration of the mucous membrane of the stomach or colon and a weak condition of the cells of the liver diminishing its antitoxic function. There was sometimes a more or less general infection of the mucous membranes, including the respiratory mucous membrane, and he had seen cases of asthma associated with intestinal toxæmia. Nervous symptoms were common. for the toxins had a special affinity for the nerve centres, hence constipation was frequently associated with neurasthenia. Neurasthenia might cause constipation. The vaso-motor centres were also affected, and this explained the unbalanced circulation—too little blood in the periphery and too much in the splanchnic area. There was also usually a great state of fatigue. The skin was usually sallow and there might be skin eruptions—e.g., eczema, psoriasis, urticaria, and pruritus, from the absorption of toxins. The joints might also be affected, and some cases of rheumatoid arthritis could be traced to an infection from the intestinal mucous membrane. In five cases he had seen purpura chiefly of the lower extremities. The treatment of alimentary toxæmia resolved itself into removing all sources of poisons from the nose and mouth as well as from the stomach and colon. Intestinal lavation with sulphur water had been very successful in his hands in the intestinal form. This was followed by an immersion bath of warm sulphur water to assist any arthritic or skin manifestation and open out the circulation, and he thought the brilliant operative measures they had heard advocated were seldom required.

Mr. J. G. TURNER, from observation of the results of treatment directed to dental sepsis only, was sure of the existence of an alimentary toxæmia due to *dental sepsis.* The components of dental sepsis and dental caries, pyorrhœa, tartar, artifact causes of sepsis, were all governed by the root-factor stagnation—stagnation of germs and soft, starchy, and sugary foods. It might be termed germ-carbohydrate stagnation. He gave the results of his observations, showing that both in man and the lower animals dental sepsis ran parallel with the occurrence of germ-carbohydrate stagnation, citing the occurrence of pyorrhœa and dental caries in South Sea Islanders and in captive monkeys. The islanders made extensive use of cocoa-nuts and captive monkeys were largely fed on bread. Jaws of the seventeenth and eighteenth centuries showed far less pyorrhœa than those of to-day. Fine ground flour was the determining factor. Dental sepsis, including the early stage of pyorrhœa, a marginal gingivitis, was as common in children as in adults. Dental sepsis was a factor for evil long before pus was an obtrusive symptom or the teeth tender, and was accompanied by fœtor which could be demonstrated by passing whisps of cotton wool between the teeth and smelling. Fœtor was as common in children as in adults. Carious teeth, ill-made fillings, ill-fitting crowns and bridges, and tooth-plates were storehouses for decomposing food and débris. The swallowing of putrefaction products played an important part in the production of alimentary toxæmia. In treatment the most radical was the safest means, in hospital practice especially so, because of the danger of artifact sepsis. Those who had not inquired would be astonished to find how many people lived comfortably with few or no teeth. He did not wish to be understood to say treatment short of extraction was useless. Most gratifying results could be obtained by local treatment if the patient could maintain the clean state so arrived at. Vaccines, he thought, would fail because of re-accumulation, and the advent of new germs or of a variant of the old, and the impossibility of preventing putrefaction Their effects might also be evanescent For prevention he urged cleanliness and a return to bread made f coarse ground meal.

Dr **ARTHUR F HERTZ** examined the evidence on which a iagnosis of toxæmia due to chronic intestinal stasis could be ade It might be gathered from what some clinicians had aid that it was possible to make a diagnosis from the ymptoms alone, but even those which were regarded as most haracteristic were by no means pathognomonic It was not ncommon to be told by a patient, who was in the habit of aking large quantities of aperients for constipation, that the ymptoms from which he suffered were better if he forgot to ake his aperient and his bowels were not opened They ppeared to be due to the absorption of poisons from he abnormally fluid fæces in his colon, and were a result f the diarrhœa produced by his aperient and not of is constipation In such cases he had often found hat the bismuth reached the rectum in the normal ime, although no aperient was taken, but the patients ad become so convinced that their bowels would not act without help that they made no attempt to open them The X rays afforded the only reliable means of determining whether a patient was suffering from chronic intestinal stasis and of ascertaining exactly what parts of the alimentary canal were at fault It was, however, first necessary to determine whether large doses of bismuth salts nterfered with the normal activity of the bowel, for it had rightly been pointed out that they were among the best drugs for combating certain forms of diarrhœa Bismuth salts only influenced those cases of diarrhœa in which excess of sulphuretted hydrogen had developed as a result of abnormal putrefaction This gas was a powerful stimulant to the intestinal movements, but it was rendered inert by combining with bismuth He now used barium sulphate instead of bismuth oxychloride, as it did not combine with sulphuretted hydrogen, and under no circumstances affected the motility of the stomach or intestines The first examination of a case of constipation by means of the X rays was made by him in 1907, after he had examined a considerable number of normal individuals. The figures that he and his collaborator had published of the average time taken for bismuth to reach different parts of the bowel in normal individuals had since been taken as a standard, and any case in which delay, when compared with this standard, had been observed had too often been diagnosed as an example of intestinal stasis The error of this was obvious, when it was remembered that their figures represented the average of considerably divergent times The so called writhing of the duodenum, which had been described as occurring in cases of intestinal stasis as a result of a supposed duodenal kink, was nothing else than the normal peristalsis and segmentation rendered more clearly visible than usual by the great quantity of bismuth containing chyme present The skiagrams which had been published as examples of the dilated duodenum, which was stated to give rise to duodenal ulcer and to be due to obstruction by a duodenal kink, really represented a duodenum of normal size, which was exceptionally full as a result of posture, as they were told that before the skiagram was taken it was necessary for the patient to lie on his right side for two or three minutes, whilst in cases of duodenal ulcer the rapid evacuation of the stomach was an additional factor In over 50 cases of uncomplicated duodenal ulcer he had not yet seen a dilated duodenum or a duodenal kink; the stomach was always hypertonic and emptied itself with unusual rapidity, the bismuth passing through the small intestine and reaching the colon with remarkable speed The constipation which was generally present was not the cause of the ulceration, as in many cases it only developed after the symptoms of ulcer had appeared, and it almost invariably disappeared as soon as the ulcer healed—whether as a result of medical treatment or of the performance of a gastro-enterostomy They had found that the bismuth containing chyme reached the end of the ileum an hour or even longer before any appreciable quantity passed into the cæcum and that the ileum was often still full four or more hours after the last traces of bismuth had left the stomach Consequently an accumulation of chyme occurred in the last few inches of the ileum, where it remained and underwent digestion actually for a longer period than in the stomach This was a result of the tonic contraction of the ileo-cæcal sphincter, the function of which was to prevent the passage of the contents of the ileum into the cæcum until sufficient time had elapsed for digestion and absorption of foodstuffs to be complete, as the chyme which reached the cæcum contained only traces of nutrient material in solution Iliac stasis was thus a normal physiological condition of the utmost importance for adequate digestion The normal iliac stasis was increased in all conditions, such as appendicitis, which led to the inhibition of the normal relaxation of the ileo cæcal sphincter The end of the ileum, as it rose from the pelvis to join the cæcum, bent in various directions; as the shadow on the screen was in one plane only, it was natural that it often appeared as if it formed one or more acute angles or kinks, it was obvious, therefore, that no conclusion of any sort could be made from skiagrams alone as to the presence or absence of kinks By palpating the abdomen during the examination it was easy to demonstrate that these "kinks" were in a large proportion of cases only apparent Although there could be no doubt that abnormal bands might occur in connexion with the terminal portion of the ilium, even though their existence could not always be demonstrated with the X rays, he did not feel convinced that they were of any importance, except in quite exceptional cases The obstruction offered by a genuine iliac kink was hardly ever as great as that normally offered by the ileo-cæcal sphincter three inches farther on In the skiagrams published to illustrate the iliac kink the lumen was not even always narrowed When it was narrowed, there was nothing to show that the narrowing did not represent a division produced by the segmentation, which normally occurred with great activity in the end of the ileum Nothing short of almost complete stenosis could lead to stasis of any importance as the contents of the ileum were always so fluid that they could pass through a very narrow passage without difficulty A true iliac kink, if it ever really led to iliac stasis, probably did so by inhibiting the relaxation of the ileo cæcal sphincter In normal individuals examined with the X rays the hepatic and splenic flexures almost invariably appeared to be acutely kinked. This again was the result of the shadow being cast in a single plane, as the limbs of the flexures belonging to the transverse colon were in front of those of the ascending and descending colon respectively, and therefore the flexures appeared to be acute, although they formed a wide angle when looked at from the side He had seen a pelvic cæcum and a dropped transverse colon just as frequently in healthy individuals as in constipated patients, and he had never been able to convince himself, when a pelvic cæcum was associated with constipation, that there was any causal relationship between the two conditions, as in the majority of cases dyschezia without delay in the cæcum or in any other part of the colon was present Ptosis of the transverse colon never led to kinking at the hepatic flexure, as this invariably dropped with it, but a sharp kink was occasionally produced at the splenic flexure, as the phreno colic ligament was stronger than any other of the intestinal attachments His investigations had shown that in a large majority of instances only part of the colon was affected in constipation In nearly half of his cases the rectum was affected alone This condition of dyschezia could be treated with success by re educating the patient to defæcate by regular habits, abdominal exercises, and graduated enemata In other cases the cæcum and ascending colon were alone affected, as soon as the bismuth got into the transverse colon, its passage to the rectum was normal in rate Such patients generally obtained relief by diet, drugs, and massage applied regularly for a prolonged period to the affected part In another group of cases the passage as far as the splenic flexure was normal in rate, but considerable difficulty was experienced in getting beyond this point This was sometimes due to severe ptosis of the transverse colon, the splenic flexure remaining fixed, and sometimes to unexplained muscular weakness of the distal part of the transverse colon Such cases could generally be relieved by the regular use of moderately large enemata without the aid of drugs or other treatment, with the exception of an abdominal support if ptosis was present The comparatively rare cases in which the whole of the bowel was involved were generally amenable to treatment by diet, massage and drugs Only when the whole of the colon was involved and thorough and prolonged medical treatment had proved completely ineffective was ileo-sigmoidostomy the rational treatment.

Mr. FRANK COLEMAN said that the odontological aspect of this subject was concerned chiefly in the sources of alimentary toxæmia, but it also had an important bearing on its consequences and treatment. The mouth acted as a source of alimentary toxæmia only in an indirect manner—viz., by the passage of its contents into the stomach and intestine, for little or no absorption took place by means of its own lining membrane. According to Dr. Andrewes' definition of alimentary toxæmia, which had been largely accepted in this discussion, "actual bacterial invasion of the blood" was excluded, and it was therefore assumed that the lining membrane of the alimentary canal remained intact and absorption took place by some process akin to osmosis, assisted no doubt by the physiological activity of the columnar cells. He mentioned this definition because in stating how the mouth might act as a source of alimentary toxæmia he referred to certain lesions for the purpose of describing how their secondary effects—viz., impairment of mastication and increase of the bacterial contents of the mouth—might play an important part in alimentary toxæmia. Granted this premise, the mouth formed a source of alimentary toxæmia in three ways: (1) Lesions of the buccal cavity, which largely fell into two classes—lesions of the teeth and lesions of the gums; (2) imperfect mastication, which might be due to inefficient teeth or want of teeth; and (3) mouth breathing. There was some overlapping of these classes; still, some such classification served a useful purpose in bringing the facts together. The first class might allow of direct bacterial invasion of the blood, but at the same time some of the bacteria or their toxins were shed into the mouth and swallowed. The pulp of a tooth, as long as its remained alive, could exert a defensive action against the invasion of micro-organisms, and if teeth could always be filled at this stage conservative dentistry would be a satisfactory branch of healing; but when once the pulp was involved by caries and its removal thereby necessitated, conservative work must be regarded as a compromise. The effect of diseased teeth had only within recent years been recognised as a fruitful source of alimentary toxæmia, so that many people still regarded the absence of discomfort in a tooth as tantamount to its harmlessness. Carious cavities in teeth that had not involved the pulp were a potential source of alimentary toxæmia, although their contained bacteria might have produced no inflammatory reaction on the tissues of the mouth, for these cavities acted as incubating chambers and greatly added to the bacterial content of the mouth, and consequently the number of bacteria swallowed. Many of the bacteria that were swallowed became disintegrated and set free intracellular toxins. If one considered the large area of infection that resulted from a suppurative periodontitis involving several tooth-sockets (roughly a square inch per socket), the correlating discharge from such an area, the favourable incubating chamber formed by a tooth-socket for the development of micro-organisms and their toxins, and the mechanical difficulties it offered for efficient drainage, was it to be denied that the mouth might be an important source of alimentary toxæmia? A gingivitis would sometimes directly infect the mucous glands of the cheek that lay opposed to the teeth. The second way in which the mouth might act as a source of toxæmia was by inefficient mastication. If mastication, and consequently insalivation, were imperfectly performed, food was swallowed before being thoroughly broken up, whilst the carbohydrate portion was only partly, if at all, converted into maltose. The effect of this were to throw more work on the stomach and small intestine and so impair digestion, besides which the bactericidal property of the gastric juice was rendered less effective on swallowed bacteria. The detergent effect of fibrous foodstuffs and the scouring action of the tongue and lips were correspondingly diminished by defective mastication, so that débris of food, mucus, and micro-organisms collected on and between the teeth. The artificial means of cleansing the mouth were insignificant in their value as compared with those brought about by efficient mastication. The third way in which the mouth might act as a source of alimentary toxæmia was brought about by mouth breathing and the inhalation of cold air, which might also be impure.

CLINICAL SECTION.

Exhibition of Clinical Cases.—Ulcerative Colitis Terminating Fatally.

A MEETING of this section was held on April 11th, Sir W. WATSON CHEYNE, Vice-President, being in the chair.

Mr. E. M. CORNER and Dr. P. H. MITCHINER showed a case of Chronic Bone Disease. The patient, a girl, had been shown before the Clinical Society on Oct. 26th, 1906. The disease of the bone was then regarded as syphilitic. Later the bony enlargements, confined to one limb and the corresponding half of the pelvis, were shown to be enchondromata. Finally the disease was regarded as a series of developmental errors whose distribution suggested the idea that they were dependent on a dystrophy due to some nervous lesion, possibly congenital. Since 1906 the patient had broken her leg and came to the hospital because union was slow and unsatisfactory. The shortening of the limb in 1906 was 2½ in; when shown it was 5¾ in., the greater part (3½ in.) being due to differences in the femurs.

Mr. CORNER also showed a case of Ossification in the Brachialis Anticus. The patient was a young man who fell on his hand a few months ago, fracturing the lower end of his radius. There was no complaint of any injury or pain in the neighbourhood of the elbow-joint. Later the patient discovered a painless lump in front of the elbow. A skiagram showed that this lump was due to some ossification in the brachialis anticus muscle. Presumably this was the result of a partial rupture of the muscle, done unconsciously at the same accident.

Mr. CORNER and Mr. C. V. ANDERSON showed a case of Recovery after Severe Electric Burns. The patient, a man aged 32, in the course of his work had an alternating current of 10,000 volts pass up his left arm and down his legs. He felt a shock and then became anæsthetic and unconscious. On rising from the ground he was dazed and unaware of the burns he had sustained. These were: 1. Of the fourth degree near the elbow; near the hand the burns were of the second and third degrees. It was noteworthy that the portion of the body making contact had slighter burns than portions of the body farther away. 2. The right foot was burned to the second and third degrees. 3. The left leg and foot were burned to the second and third degrees. The burns were widely distributed. They were sufficiently severe to require grafting. During convalescence signs gradually set in indicating a lesion of his left median nerve, that of the arm up which the current passed. These signs became more marked, and it was supposed that the nerve was burned or caught in the scar. It was exposed and found to have no lesion detectable by the naked eye. The signs and symptoms of this lesion increased, and then began to clear up, which they did completely. The pathological lesion might have been due to the passage in the nerve of an electric current in the opposite direction to the normal passage of impulses, or to some electrolytic change. No record of a similar condition was found.
